Nonlocal elastodynamics and fracture†

Robert P. Lipton∗ Prashant K. Jha‡

July 21, 2020

Abstract

A nonlocal field theory of peridynamic type is applied to model the brittle fracture problem. The elastic fields obtained from the nonlocal model are shown to converge in the limit of vanishing non-locality to solutions of classic plane elastodynamics associated with a running crack.

Keywords: Brittle Fracture, Peridynamics, Nonlinear, Nonlocal, Elastodynamic

AMS Subject 34A99, 74R99

1 Introduction

Fracture can be viewed as a collective interaction across large and small length scales. With the application of enough stress or strain to a brittle material, atomistic scale bonds will break, leading to fracture of the macroscopic specimen. From a modeling perspective fracture should appear as an emergent phenomena generated by an underlying field theory eliminating the need for a supplemental kinetic relation describing crack growth. The displacement field inside the body for points $x$ at time $t$ is written $u(x, t)$. The peridynamic model [30], [31], is described by the nonlocal balance of linear momentum of the form

$$\rho u_{tt}(x, t) = \int_{\mathcal{H}_\epsilon(x)} f(y, x) \, dy + b(x, t) \tag{1.1}$$

where $\mathcal{H}_\epsilon(x)$ is a neighborhood of $x$, $\rho$ is the density, $b$ is the body force density field, and $f$ is a material-dependent constitutive law that represents the force density that a point $y$ inside the neighborhood exerts on $x$ as a result of the deformation field. The radius $\epsilon$ of the neighborhood is referred to as the horizon. Here all points satisfy the same field equation (1.1). The displacement fields and fracture evolution predicted by the nonlocal model should agree with the dynamic fracture of specimens when the length scale of non-locality is sufficiently small. In this respect numerical simulations are compelling, see for example [3], [32], and [34].

The displacement for the nonlocal theory is examined in the limit of vanishing non-locality. This is done for a class of peridynamic models with nonlocal forces derived from double well potentials see, [19]. The term double well describes the force potential between two points. One of the wells is degenerate and appears at infinity while the other is at zero strain. For small strains the nonlocal force is linearly elastic but for larger strains the force begins to soften and then approaches zero after reaching a critical strain. This type of nonlocal model is called a cohesive model. Fracture energies

of this type have been defined for displacement gradients in \cite{35} with the goal of understanding fracture as a phase transition in the framework of \cite{11}.

We theoretically investigate the limit of the displacements for the cohesive model as the length scale $\epsilon$ of nonlocal interaction goes to zero. All information on this limit is obtained from what is known from the nonlocal model for $\epsilon > 0$. In this paper the single edge notch specimen is considered as given in figure 1 and the target theory governing the evolution of displacement fields is identified when $\epsilon = 0$. One of the hallmarks of peridynamic simulations is localization of defect sets with horizon as $\epsilon \to 0$. Theoretically localization of the jump set of the displacement is established as $\epsilon \to 0$ in \cite{18}, \cite{19} where the limiting displacement is shown to be an $SBD^2(D)$ valued function for almost all times $t \in [0, T]$, see section 3. The nonlocal cohesive model converges to a dynamic model having bounded Griffith fracture energy associated with brittle fracture and elastic displacement fields satisfying the elastic wave equation \cite{18}, \cite{19} away from the fractures. This can be seen for arbitrarily shaped specimens with smooth boundary in two and three dimensions. However the explicit traction law relating the crack boundary to the elastic field lies out side the scope of that analysis.

This paper builds on earlier work and provides a global description of the limit dynamics describing elastic fields surrounding a crack for the single edge notch pulled apart by traction forces on its top and bottom edges. The objective of this paper is to show that the elastic fields seen in the nonlocal model are consistent with those in the local model in the limit of vanishing horizon. The analysis given here shows that it is possible to recover the boundary value problem for the linear elastic displacement given by Linear Elastic Fracture Mechanics inside a cracking body as the limit of a nonlocal fracture model. To illustrate this a family of initial value problems given in the nonlocal formulation is prescribed. The family is parameterized by horizon size $\epsilon$. The crack motion for $\epsilon > 0$ is prescribed by the solutions of the nonlocal initial value problem. It is shown that up to subsequences that as $\epsilon \to 0$ the displacements associated with the solution of the nonlocal model converge in mean square uniformly in time to the limit displacement $u^0(x, t)$ that satisfies:

- Prescribed inhomogeneous traction boundary conditions.
- Balance of linear momentum as described by the linear elastic wave equation off the crack.
- Zero traction on the sides of the evolving crack.
- The set on which the elastic displacement jumps is a subset of the crack set.
- The limiting crack motion is determined by the sequence of nonlocal problems for $\epsilon > 0$ and is obtained in the $\epsilon = 0$ limit.

The first four items deliver the boundary conditions, elastodynamic equations, traction boundary conditions on the crack, and correlation between displacement jumps and crack set articulated in the
theory of dynamic Linear Elastic Fracture Mechanics (LEFM) \[14, 27, 2, 33\]. The \( \epsilon \to 0 \) limit of displacement fields for the nonlocal model is seen to be a weak solution for the wave equation on a time dependent domain recently defined in the work of \[10\], see theorem 3.4. Here the time dependent domain is given by the domain surrounding the moving crack. This establishes a rigorous connection between the nonlocal fracture formulation using a peridynamic model derived from a double well potential and the wave equation posed on cracking domains given in \[10\]. If one assumes a more general crack structure for the nonlocal problem then a connection to the local problem for more general time dependent domains can be made, this is discussed in the conclusion.

The analysis treats a dynamic problem and compactness methods suited to the balance of momentum for nonlocal - nonlinear operators, are applied, see lemma 3.2 and theorem 3.2. Proceeding this way delivers the zero traction condition on the crack lips for the fracture model in the local limit. Another issue is to prescribe body forces for the nonlocal model that transform into boundary tractions for the local model. In this paper a suitable layer of force is prescribed adjacent to the boundary of the sample for the nonlocal model. It is motivated by the one proposed in \[34\]. The layer of force is shown to converge to the standard traction boundary conditions seen in local models, see lemma 3.1. This theoretically corroborates the numerical experiments with the nonlocal model carried out in \[34\]. It is pointed out that the nonlocal model considered here is elastic, so cracks can heal if the strain across the crack drops below the critical value. However, in this paper the initial conditions and boundary conditions are chosen such that the specimen is under tensile strain and pulled apart so the crack has no opportunity to heal. More complex models \[21\] involving dissipation and non-monotone or cyclic load paths lie outside the scope of the paper and provide interesting avenues for future research.

The nonlocal model is an example of several new approaches to dynamic fracture modeling. These include solution of the wave equation on cracking domains \[8, 9, 10, 26\], phase field methods \[5, 6, 24, 29\], and peridynamics \[30, 31, 3, 34\]. In the absence of fracture and dynamics the \( \Gamma \) convergence approach has been applied to peridynamic boundary value problems. The nonlocal formulations are shown to converge to equilibrium boundary value problems for hyperelastic and elastic materials as \( \epsilon \to 0 \), see \[4, 25\]. It is noted that the aforementioned references while relevant to this work are only a few from a rapidly expanding literature.

The paper is organized as follows: In section 2 the nonlocal constitutive law as derived from a double well potential is described and the nonlocal boundary value problem describing crack evolution is given. Section 3 provides the principle results of the paper and describes the convergence of the displacement fields given in the nonlocal model to the elastic displacement field satisfying, the linear wave equation off the crack set, zero Neumann conditions on the crack, and traction boundary conditions. Existence and uniqueness for the nonlocal problems are established in \[4\]. The convergence theorems are proved in sections 5 and 6. The proof that the limit displacement is a weak solution of the wave equation on a time dependent domain is given in section 7. The results are summarized in the conclusion section 8.

### 2 Nonlocal Elastodynamics

In this section we formulate the nonlocal dynamics as an initial boundary value problem driven by a layer of force adjacent to the boundary. Here all quantities are non-dimensional. Define the region \( D \) given by a notched rectangle with rounded corners, see figure 1. The domain lies within the rectangle \( \{0 < x_1 < a; -b/2 < x_2 < b/2\} \) and the notch originates on the left side of the specimen and is of thickness \( 2d \) and total length \( \ell(0) \) with a circular tip and rounded corners, see figure 1. The domain is subject to plane strain loading and we will assume small deformations so the deformed configuration is the same as the reference configuration. We have \( \mathbf{u} = \mathbf{u}(\mathbf{x}, t) \) as a function of space and time but will suppress the \( \mathbf{x} \) dependence when convenient and write \( \mathbf{u}(t) \). The tensile strain \( S \)
between two points $x, y$ in $D$ along the direction $e_{y-x}$ is defined as

$$S(y, x, u(t)) = \frac{u(y, t) - u(x, t)}{|y - x|} \cdot e_{y-x}, \quad (2.1)$$

where $e_{y-x} = \frac{y - x}{|y - x|}$ is a unit vector and "·" is the dot product.

The nonlocal force $f$ is defined in terms of a double well potential that is a function of the strain $S(y, x, u(t))$. The force potential is defined for all $x, y$ in $D$ by

$$W^r(S(y, x, u(t))) = J^r(|y - x|) \frac{1}{e^2 \omega_2 |y - x|} \Psi(\sqrt{|y - x|} |S(y, x, u(t))|) \quad (2.2)$$

where $W^r(S(y, x, u(t)))$ is the pairwise force potential per unit length between two points $x$ and $y$. Here, the influence function $J^r(|y - x|)$ is a measure of the influence that the point $y$ has on $x$. Only points inside the horizon can influence $x$ so $J^r(|y - x|)$ is nonzero for $|y - x| < \epsilon$ and is zero otherwise. We take $J^r$ to be of the form: $J^r(|y - x|) = J(|y - x|/\epsilon)$ with $J(r) = 0$ for $r \geq 1$ and $0 \leq J(r) \leq M < \infty$ for $r < 1$.

The force potential is described in terms of its potential function and to fix ideas $\Psi$ is given by

$$\Psi = h(r^2) \quad (2.3)$$

where $h$ is concave, see figure 2(a). Here $\omega_2$ is the area of the unit disk and $e^2 \omega_2$ is the area of the horizon $\mathcal{H}_c(x)$. The potential function $\Psi$ represents a convex-concave potential such that the associated force acting between material points $x$ and $y$ are initially elastic and then soften and decay to zero as the strain between points increases, see figure 2(b). The force between $x$ and $y$ is referred to as the bond force. The first well for $W^r(S(y, x, u(t)))$ is at zero tensile strain and the potential function satisfies

$$\Psi(0) = \Psi'(0) = 0. \quad (2.4)$$

The well for $W^r(S(y, x, u(t)))$ in the neighborhood of infinity is characterized by the horizontal asymptote $\lim_{s \to \infty} \Psi(S) = C^+$, see figure 2(a). The critical tensile strain $S_c > 0$ for which the force begins to soften is given by the inflection point $r^c > 0$ of $g$ and is

$$S_c = \frac{r^c}{\sqrt{|y - x|}}, \quad (2.5)$$

and $S_\gamma$ is the strain at which the force goes to zero

$$S_\gamma = \frac{r^\gamma}{\sqrt{|y - x|}}. \quad (2.6)$$

We assume here that the potential functions are bounded and are smooth. It is pointed out that for this modeling the bond force in compression allows for eventual softening. However one can easily generalize the analysis to handle an asymmetric bond force that resists compression.

### 2.1 Peridynamic equation of motion

The potential energy of the motion is given by

$$PD^r(u) = \int_D \int_{\mathcal{H}_c(x) \cap D} |y - x| W^r(S(y, x, u(t))) \, dy \, dx. \quad (2.7)$$

We consider single edge notched specimen $D$ pulled apart by an $\epsilon$ thickness layer of body force on the top and bottom of the domain consistent with plain strain loading. In the nonlocal setting the
“traction” is given by the layer of body force on the top and bottom of the domain. For this case the body force is written as

$$
b'(x, t) = e^2\epsilon^{-1}g(x_1, t)\chi_+^\epsilon(x_1, x_2) \text{ on the top layer and } 
\ b'(x, t) = -e^2\epsilon^{-1}g(x_1, t)\chi_-^\epsilon(x_1, x_2) \text{ on the bottom layer,} (2.8)$$

where $e^2$ is the unit vector in the vertical direction, $\chi_+^\epsilon$ and $\chi_-^\epsilon$ are the characteristic functions of the boundary layers given by

$$
\chi_+^\epsilon(x_1, x_2) = 1 \text{ on } \{\theta < x_1 < a - \theta, b/2 - \epsilon < x_2 < b/2\} \text{ and 0 otherwise,} \n\chi_-^\epsilon(x_1, x_2) = 1 \text{ on } \{\theta < x_1 < a - \theta, -b/2 < x_2 < -b/2 + \epsilon\} \text{ and 0 otherwise,} (2.9)$$

where $\theta$ is the radius of curvature of the rounded corners of $D$. The top and bottom traction forces are equal and in opposite directions and $g(x_1, t) > 0$. We take the function $g$ to be smooth and bounded in the variables $x_1$ and $t$ and define $g$ on $\partial D$ such that

$$
g = \pm e^2g \text{ on } \{\theta \leq x_1 \leq a - \theta, x_2 = \pm b/2\} \text{ and } g = 0 \text{ elsewhere on } \partial D. (2.10)$$

For any in-plane rigid body motion $\mathbf{w}(x) = \Omega \times x + c$ where $\Omega$ and $c$ are constant vectors we see that

$$
\int_D b' \cdot \mathbf{w} \, dx = 0 \text{ and } S(y, x, \mathbf{w}) = 0, (2.11)$$

and we show in lemma 3.1 that $b'$ is a bounded linear functional on an appropriate Sobolev space and converges as $\epsilon \to 0$ to a boundary traction.

For future reference we denote the space of all square integrable fields orthogonal to rigid body motions in the $L^2$ inner product by

$$\tilde{L}^2(D; \mathbb{R}^2). (2.12)$$

In this treatment the density $\rho$ is assumed constant and we define the Lagrangian

$$L(u, \partial_t u, t) = \frac{\rho}{2}||\dot{u}||^2_{L^2(D; \mathbb{R}^2)} - PD'(u) + \int_D b' \cdot u \, dx,$$

where $\dot{u} = \frac{\partial u}{\partial t}$ is the velocity. The action integral for a time evolution over the interval $0 < t < T$, is given by

$$I = \int_0^T L(u, \partial_t u, t) \, dt. (2.13)$$
We suppose $u'(t)$ is a stationary point and $w(t)$ is a perturbation and applying the principal of least action gives the nonlocal dynamics

$$
\rho \int_0^T \int_D \dot{u}'(x, t) \cdot \dot{w}(x, t) \, dx \, dt
$$

$$
= \int_0^T \int_D \int_{\mathcal{H}_e(x) \cap D} |y - x| \partial_S \mathcal{W}'(S(y, x, u'(t))) S(y, x, w(t)) \, dy \, dx \, dt
$$

$$
- \int_0^T \int_D b'(x, t) \cdot \dot{w}(x, t) \, dx \, dt.
$$

and an integration by parts gives the strong form

$$
\rho \ddot{u}'(x, t) = \mathcal{L}'(u')(x, t) + b'(x, t), \quad \text{for } x \in D. \tag{2.15}
$$

Here $\mathcal{L}'(u')$ is the peridynamic force

$$
\mathcal{L}'(u') = \int_{\mathcal{H}_e(x) \cap D} f'(y, x) \, dy
$$

and $f'(x, y)$ is given by

$$
f'(x, y) = 2\partial_S \mathcal{W}'(S(y, x, u'(t))) e_y - x, \tag{2.17}
$$

where

$$
\partial_S \mathcal{W}'(S(y, x, u'(t))) = \frac{1}{e^{3\omega_2}} \frac{J'(|y - x|)}{|y - x|} \partial_S \Psi(\sqrt{|y - x|} S(y, x, u'(t))). \tag{2.18}
$$

The dynamics is complemented with the initial data

$$
u'(x, 0) = u_0(x), \quad \partial_t u'(x, 0) = v_0(x). \tag{2.19}
$$

Where $u_0$ and $v_0$ lie in $L^2(D; \mathbb{R}^2)$.

The initial value problem for the nonlocal evolution given by (2.15) and (2.19) or equivalently by (2.14) and (2.19) has a unique solution in $C^0([0, T]; L^2(D; \mathbb{R}^2))$, see section 4. Application of Gronwall’s inequality shows that the nonlocal evolution $u'(x, t)$ is uniformly bounded in the mean square norm over the time interval $0 < t < T$,

$$
\max_{0 < t < T} \left\{ \|u'(x, t)\|_{L^2(D; \mathbb{R}^2)}^2 \right\} < K, \tag{2.20}
$$

where the upper bound $K$ is independent of $\epsilon$ and depends only on the initial conditions and body force applied up to time $T$, see [19].

### 2.2 Failure zone and softening zone geometry

The failure zone and softening zone are introduced and described for the $\epsilon > 0$ model. The failure zone $FZ'(t)$ represents the crack in the nonlocal model at a given time $t$. This is the set of pairs $x$ and $y$ with $|y - x| < \epsilon$ for which the force $f'(x, y)$ acting between them is zero. In this problem the domain and body force adjacent to the upper and lower boundaries are symmetric with respect to the $x_2 = 0$ axis, see (2.8). The body force is perpendicular to the $x_2 = 0$ axis and points in the $e^2$ direction on the top boundary layer and the $-e^2$ direction on the bottom boundary layer. Choosing initial conditions appropriately the solution to the initial value problem has its first component $u'_1$ even with respect to the $x_2 = 0$ axis and second component $u'_2$ odd for $t \in [0, T]$. For the time dependent body force chosen here the failure is in tension and confined to a neighborhood of the
for every \( \epsilon > 0 \) and the sample, i.e., \( \ell^\epsilon_S \) by the failure zone is defined by a centerline lying on the \( x_2 = 0 \) axis. The tip of the notch is defined to be the point \((x_1 = \ell(0), x_2 = 0)\). The failure zone centerline is

\[
C^\epsilon = \{\ell(0) \leq x_1 \leq \ell^\epsilon(t), x_2 = 0\}. 
\tag{2.21}
\]

The failure zone is written as

\[
F^\epsilon_z(t) = \{x \text{ and } y \in D, |y - x| < \epsilon : x + s(y - x) \cap C^\epsilon(t) \neq \emptyset, \text{ for some } s \in [0, 1]\}, \tag{2.22}
\]

The centerline is shown in figure 3 and the failure zone is the shaded region. Here \( f^\epsilon(x, y) = 0 \) for \( x \) and \( y \) in \( F^\epsilon_z(t) \). The crack motion is prescribed by the monotonically increasing function \( \ell^\epsilon(t) \) for every \( \epsilon > 0, t \in [0, T] \). We will assume that the crack does not propagate all the way through the sample, i.e., \( \ell^\epsilon(T) < a - \delta \), for every \( \epsilon \) where \( \delta \) is a small fixed positive constant.

The total traction force on on the layer of thickness \( \epsilon \) above the failure zone centerline exerted by the body below the failure zone centerline is null and vice versa. Associated with the failure zone is the softening zone. The softening zone \( S^\epsilon_z(t) \) is the set of pairs \( x \) and \( y \) with \( |y - x| < \epsilon \) separated by the \( x_2 = 0 \) axis such that the force \( f^\epsilon(x, y) \) between them is non-increasing with increasing strain. From this it is clear that \( F^\epsilon_z(t) \subset S^\epsilon_z(t) \). Furthermore at the leading edge of the crack one sees force softening between points \( x \) and \( y \) separated by less than \( \epsilon \) on either side of the \( x_2 = 0 \) axis. As the crack centerline moves forward passing between \( x \) and \( y \) the force between \( x \) and \( y \) decreases to zero, see figure 3. That is given \( t \) there is a later time \( t + \Delta t \) for which \( F^\epsilon_z(t + \Delta t) = S^\epsilon_z(t) \). The process zone where the bonds have softened but not failed, i.e., \( x, y \in S^\epsilon_z(t) \setminus F^\epsilon_z(t) \) is of length proportional to \( \epsilon \). The softening zone \( S^\epsilon_z(t) \) is specified through a softening zone centerline. The force between two points \( x \) and \( y \) separated by the softening zone centerline decreases with time. The centerline is

\[
S^\epsilon(t) = \{\ell(0) \leq x_1 \leq \ell^\epsilon(t) + C\epsilon, x_2 = 0\}, \tag{2.23}
\]

where \( C \) is a positive constant. The softening zone is written as

\[
S^\epsilon_z(t) = \{x \text{ and } y \in D, |y - x| < \epsilon : x + s(y - x) \cap S^\epsilon(t) \neq \emptyset, \text{ for some } s \in [0, 1]\}. \tag{2.24}
\]

The strain \( S(y, x, u^\epsilon(t)) \) is decomposed for \( x \) and \( y \) in \( D \) and \( |y - x| < \epsilon \) as

\[
S(y, x, u^\epsilon(t)) = S(y, x, u^\epsilon(t))^− + S(y, x, u^\epsilon(t))^+ \tag{2.25}
\]

where

\[
S(y, x, u^\epsilon(t))^− = \begin{cases} S(y, x, u^\epsilon(t)), & \text{if } |S(y, x, u^\epsilon(t))| < S_\epsilon \\ 0, & \text{otherwise} \end{cases} \tag{2.26}
\]

and

\[
S(y, x, u^\epsilon(t))^+ = \begin{cases} S(y, x, u^\epsilon(t)), & \text{if } |S(y, x, u^\epsilon(t))| \geq S_\epsilon \\ 0, & \text{otherwise} \end{cases} \tag{2.27}
\]

with

\[
S(y, x, u^\epsilon(t))^− = \{(x, y) \notin S^\epsilon_z(t)\},
\]

\[
S(y, x, u^\epsilon(t))^+ = \{(x, y) \in S^\epsilon_z(t)\}. \tag{2.28}
\]

In the next section we recover the dynamics in the limit of vanishing horizon with failure zone and softening zone given by \( (2.22) \) and \( (2.24) \). The equations \( (2.22) \) and \( (2.24) \) constitute the hypothesis on the crack structure for the nonlocal model. For the loading prescribed here \( (2.22) \) and \( (2.24) \) naturally emerge and are a consequence of the symmetry of solution \( u^\epsilon(x, t) \), this is seen in simulations 17.
3 Convergence of nonlocal elastodynamics to elastic fields in Linear Elastic Fracture Mechanics

The crack structure is prescribed by $\ell^\epsilon(t)$ of (2.21) together with (2.22), and (2.24), and the elastic fields $u^\epsilon$ are solutions of (2.15) and (2.19). The crack structure for $\epsilon > 0$ is summarized in the following hypothesis:

**Hypothesis 3.1** (Crack Structure for $\epsilon > 0$). The moving domain associated with the defect is prescribed by $\ell^\epsilon(t)$ of (2.21), and the failure zone and softening zone are given by (2.22), and (2.24).

Given hypothesis 3.1 we now describe the convergence of $u^\epsilon$ to $u^0$ to see that $u^0$ satisfies the boundary value problem for the elastic field of LEFM for a running crack given in [14]. Recall $\ell^\epsilon(t)$ is monotone increasing with time and bounded so from Helly’s selection theorem we can pass to a subsequence if necessary to assert that $\ell^\epsilon_n(t) \to \ell^0(t)$ point wise for $t \in [0, T]$, where $\ell^0(t)$ is monotone increasing with time and bounded. This delivers the crack motion for the $\epsilon = 0$ problem described by the crack

$$\Gamma = \{\ell(0) \leq x_1 \leq \ell^0(t), x_2 = 0\}, \quad t \in [0, T].$$  

(3.1)

Here $\tau < t$ implies $\Gamma^\tau \subset \Gamma_t$. The time dependent domain surrounding the crack is defined as $D_t = D \setminus \Gamma_t$, see figure 3.

Next we describe the convergence of body force, velocity, and acceleration given by the $\epsilon > 0$ initial value problems (2.15) and (2.19) to their $\epsilon = 0$ counterparts. The convergence of the elastic displacement field, velocity field and acceleration field are described in terms of suitable Hilbert space topologies. The space of strongly measurable functions $w : [0, T] \to L^2(D; \mathbb{R}^2)$ that are square integrable in time is denoted by $L^2(0, T; \dot{L}^2(D; \mathbb{R}^2))$. Additionally we recall the Sobolev space $H^1(D; \mathbb{R}^2)$ with norm

$$\|w\|_{H^1(D; \mathbb{R}^2)} := \left( \int_D |w|^2 \, dx + \int_D |\nabla w|^2 \, dx \right)^{1/2}.  

(3.2)$$

The subspace of $H^1(D; \mathbb{R}^2)$ containing all vector fields orthogonal to the rigid motions with respect to the $L^2(D; \mathbb{R}^2)$ inner product is written

$$\dot{H}^1(D; \mathbb{R}^2).  

(3.3)$$

The Hilbert space dual to $\dot{H}^1(D; \mathbb{R}^2)$ is denoted by $\dot{H}^1(D; \mathbb{R}^2)'$. The set of functions strongly square integrable in time taking values in $H^1(D; \mathbb{R}^2)'$ for $0 \leq t \leq T$ is denoted by $L^2(0, T; \dot{H}^1(D; \mathbb{R}^2))$. These Hilbert spaces are well known and related to the wave equation, see [12].

The body force given in (2.15) is written as $b^\epsilon(t)$ and we state the following lemma.
Lemma 3.1. There is a positive constant $C$ independent of $\epsilon_n$ and $t \in [0, T]$ such that

$$\langle b^n(t), w \rangle \leq C \|w\|_{H^1(D, \mathbb{R}^2)}, \text{ for all } \epsilon_n > 0 \text{ and } w \in H^1(D, \mathbb{R}^2),$$

where $(\cdot, \cdot)$ is the duality paring between $\dot{H}^1(D, \mathbb{R}^2)$ and its Hilbert space dual $\dot{H}^1(D, \mathbb{R}^2)'$. In addition there exists $b^0(t)$ such that $b^n \rightharpoonup b^0$ in $L^2(0, T; \dot{H}^1(D, \mathbb{R}^2)')$ and

$$\langle b^0(t), w \rangle = \langle g(t), w \rangle := \int_{\partial D} g(t) \cdot w \, d\sigma,$$

for all $w \in \dot{H}^1(D, \mathbb{R}^2)$, where $g(t)$ is defined by (2.14) and $g \in H^{-1/2}(\partial D)^2$.

The traction force (3.5) delivers loading consistent with a mode one crack in the local model given by LEM. For ease of exposition we defer the proof of lemma 3.1 as well as proofs of all other theorems introduced here to sections 5 and 6.

Passing to subsequences as necessary we obtain the convergence of the elastic displacement field, velocity field, and acceleration field given by

Lemma 3.2.

$$u^n \rightharpoonup u^0 \text{ strong in } C([0, T]; \dot{L}^2(D, \mathbb{R}^2))$$
$$u^n \rightharpoonup u^0 \text{ weakly in } L^2(0, T; \dot{L}^2(D, \mathbb{R}^2))$$
$$\ddot{u}^n \rightharpoonup \ddot{u}^0 \text{ weakly in } L^2(0, T; \dot{H}^1(D, \mathbb{R}^2)'),$$

where $u^0(t)$ and $\ddot{u}^0(t)$ are distributional derivatives in time.

With the additional caveat that

$$\sup_{[0, T]} \sup_{\epsilon > 0} \|\ddot{u}^\epsilon(t)\|_{L^\infty(D, \mathbb{R}^2)} < \infty,$$

the limit evolution $u^0(x, t)$ is seen to be a special function of bounded deformation $SBD(D)$ for almost all times [18] and [19]. We will include (3.7) in the hypotheses of subsequent theorems when we make use of the fact that $u^0$ belongs to $SBD(D)$. Functions $u \in SBD(D)$ belong to $L^1(D, \mathbb{R}^d)$ (where $d = 2$ in this work) and are approximately continuous, i.e., have Lebesgue limits for almost every $x \in D$ given by

$$\lim_{\epsilon \searrow 0} \frac{1}{\omega_2 \epsilon^2} \int_{\mathcal{H}_\epsilon(x)} |u(y) - u(x)| \, dy = 0,$$

where $\mathcal{H}_\epsilon(x)$ is the ball of radius $\epsilon$ centered at $x$ and $\omega_2 \epsilon^2$ is its area given in terms of the area of the unit disk $\omega_2$ times $\epsilon^2$. The set of points in $D$ which are not points of approximate continuity is denoted by $S_u$. A subset of these points are given by the jump set $\mathcal{J}_u$. The jump set is defined to be the set of points of discontinuity which have two different one sided Lebesgue limits. One sided Lebesgue limits of $u$ with respect to a direction $\nu_u(x)$ are denoted by $u^-(x)$, $u^+(x)$ and are given by

$$\lim_{\epsilon \searrow 0} \frac{1}{\epsilon \omega_2} \int_{\mathcal{H}_\epsilon^-(x)} |u(y) - u^-(x)| \, dy = 0,$$
$$\lim_{\epsilon \searrow 0} \frac{1}{\epsilon \omega_2} \int_{\mathcal{H}_\epsilon^+(x)} |u(y) - u^+(x)| \, dy = 0,$$

where $\mathcal{H}_\epsilon^-(x)$ and $\mathcal{H}_\epsilon^+(x)$ are given by the intersection of $\mathcal{H}_\epsilon(x)$ with the half spaces $(y - x) \cdot \nu_u(x) < 0$ and $(y - x) \cdot \nu_u(x) > 0$ respectively. $SBD(D)$ functions have jump sets $\mathcal{J}_u$, that are countably rectifiable. Hence they are described by a countable number of components $K_1, K_2, \ldots$, contained within smooth manifolds, with the exception of a set $K_0$ that has zero 1 dimensional Hausdorff measure [1]. The one dimensional Hausdorff measure of $\mathcal{J}_u$ agrees with the one dimensional Lesbegue
Theorem 3.1. The displacement $u^0$ is in $SBD^2(D)$ for a.e. $t \in (0,T)$ and its first component denoted by $u^0_1(x_1,x_2)$ is even with respect to the $x_2=0$ axis and the second component of the displacement denoted by $u^0_2(x_1,x_2)$ is odd with respect to the $x_2=0$ axis and $u^0_2(x_1,x_2) = 0$, $\mathcal{H}^1$ a.e. for $\{t^0(t) < x_1 < a, x_2 = 0\}$. The jump set of $u^0$ is contained inside the crack $\Gamma_1$, $t \in [0,T]$. 

measure and $\mathcal{H}^1(\mathcal{J}_u) = \sum_i \mathcal{H}^1(K_i)$. The strain of a displacement $u$ belonging to $SBD(D)$, written as $\mathcal{E}_{ij} u^0(t) = (\partial_{x_j} u^0_t + \partial_{x_i} u^0_t)/2$, is a generalization of the classic local strain tensor and is related to the nonlocal strain $S(y,x,u^0)$ by

$$
\lim_{\epsilon \to 0} \frac{1}{\epsilon^2 \omega_2} \int_{\mathcal{H}_e(x)} |S(y,x,u^0) - \mathcal{E} u^0(x) \epsilon \cdot \epsilon| \, dy = 0,
$$

(3.10)

for almost every $x$ in $D$ with respect to 2-dimensional Lebesgue measure $\mathcal{L}^2$. The symmetric part of the distributional derivative of $u$, $\mathcal{E} u = 1/2 (\nabla u + \nabla u^T)$ for $SBD(D)$ functions is a $2 \times 2$ matrix valued Radon measure with absolutely continuous part with respect to two dimensional Lebesgue measure described by the density $\mathcal{E} u$ and singular part described by the jump set $\mathcal{J}_u$ and

$$
\langle \mathcal{E} u, \Phi \rangle = \int_D \sum_{i,j=1}^d \mathcal{E} u_{ij} \Phi_{ij} \, dx + \int_{\mathcal{J}_u} \sum_{i,j=1}^d (u^+_i - u^-_i) n_j \Phi_{ij} \, d\mathcal{H}^1,
$$

(3.11)

for every continuous, symmetric matrix valued test function $\Phi$. In the sequel we will write $[u] = u^+ - u^-$. The limit dynamics and LEFM energy are expressed in terms of elastic moduli $\lambda$ and $\mu$ and fracture toughness $G$. These are calculated directly from the nonlocal potential (2.2). Here we have taken the choice $\Psi(r) = h(r^2)$ and the elastic moduli are given by

$$
\mu = \lambda = M \frac{1}{4} h'(0),
$$

(3.12)

where the constant $M = \int_0^1 r^2 J(r) \, dr$. The elasticity tensor is given by

$$
\mathcal{C}_{ijkl} = 2\mu \left( \frac{\delta_{ik} \delta_{jl} + \delta_{il} \delta_{jk}}{2} \right) + \lambda \delta_{ij} \delta_{kl},
$$

(3.13)

and

$$
G_e = \frac{4}{\pi} \int_0^1 h(S_x) r^2 J(r) \, dr.
$$

(3.14)

The limit evolution has a bounded Griffith surface energy and elastic energy given by

$$
\int_D \mu |\mathcal{E} u^0(t)|^2 + \frac{\lambda}{2} |\text{div} u^0(t)|^2 \, dx + G \mathcal{H}^1(\mathcal{J} u^0) \leq C,
$$

(3.15)

for $0 \leq t \leq T$, where $\mathcal{J} u^0(t)$ denotes the evolving jump set inside the domain $D$, across which the displacement $u^0$ has a jump discontinuity and $\mathcal{H}^1$ is one dimensional Hausdorff measure, see [18] and [19]. Because $u^0$ has bounded energy (3.15) we see that $u^0$ also belongs to $SBD^2(D)$. Here $SBD^2(D)$ is the set of $SBD(D)$ functions with square integrable strain $\mathcal{E} u$ and jump set with bounded $\mathcal{H}^1$ measure. It has been recently shown in [7] that for $u \in SBD^2(D)$ that

$$
\mathcal{H}^1(S_u \setminus \mathcal{J}_u) = 0.
$$

(3.16)

It is remarked that the equality $\lambda = \mu$ appearing in (3.12) is a consequence of the central force nature of the nonlocal interaction mediated by (2.2). While non-central force potentials can deliver a larger class of energy-volume-shape change relations [31] a central force potential is been chosen to illustrate the ideas.

The symmetry of the limit displacement $u^0$ as an element of $SBD^2(D)$ follows from the symmetry of $u^0$. 

Theorem 3.1. The displacement $u^0$ is in $SBD^2(D)$ for a.e. $t \in (0,T)$ and its first component denoted by $u^0_1(x_1,x_2)$ is even with respect to the $x_2=0$ axis and the second component of the displacement denoted by $u^0_2(x_1,x_2)$ is odd with respect to the $x_2=0$ axis and $u^0_2(x_1,x_2) = 0$, $\mathcal{H}^1$ a.e. for $\{t^0(t) < x_1 < a, x_2 = 0\}$. The jump set of $u^0$ is contained inside the crack $\Gamma_1$, $t \in [0,T]$. 

10
Theorem 3.2. For all \( \tau \in (0, T) \), \( \bar{u}^0(x, t) \) belongs to \( W^\pm(D_\beta(\tau))' \) for almost all \( t \in (\tau, T) \) and

\[
\bar{u}^\pm \rightharpoonup \bar{u}^0 \text{ weakly in } L^2(\tau, T; W^\pm(D_\beta(\tau))').
\]

Since \( \bar{u}^0 \) belongs to \( W^\pm(D_\beta(\tau))' \) we introduce the normal traction \( \mathcal{E}\mathcal{E}u^0n \) defined on the crack lips for \( (\tau, T) \) and \( \partial D \) in the generalized sense. In order to describe the generalized traction we introduce trace spaces compatible with the crack geometry. For \( t \in [0, t] \) we introduce the weight defined on \( \partial D^\pm_\beta(t) \) given by

\[
\alpha_\pm(x_1, x_2, \beta) = \begin{cases} 
\min\{1, \sqrt{\ell^0(t) - \beta - x_1}\}, & \text{on } x_2 = 0 \\
\min\{1, \sqrt{\pm x_2}\}, & \text{on } x_1 = a, \pm x_2 > 0 \\
1, & \text{otherwise.}
\end{cases}
\]

and the trace spaces \( H^{1/2}_{\partial D^\pm_\beta(t)} \) given in \([22]\) are defined by all functions \( w \) in \( H^{1/2}(\partial D^\pm_\beta(t))^2 \) with

\[
\int_{\partial D^\pm_\beta} |w(x)|^2 \alpha_\pm^{-1}(x, \beta) dx < \infty.
\]

The dual to \( H^{1/2}_{\partial D^\pm_\beta(t)} \) is \( H^{1/2}_{\partial D^\pm_\beta(t)} \). This type of trace space is employed for problems of mechanical contact in \([16]\), see also \([28]\). The trace operator \( \gamma \) is a continuous linear map from \( W^\pm(D_\beta(t)) \) onto \( H^{1/2}_{\partial D^\pm_\beta(t)} \), see \([22]\). Additionally the trace operator \( \gamma \) is a continuous linear map from \( H(D, \mathbb{R}^2) \) onto \( H^{1/2}(\partial D)^2 \).

In what follows the duality bracket for Hilbert spaces \( H \) and their dual \( H' \) is defined by \( \langle \cdot, \cdot \rangle \), where the first argument is an element of \( H' \) and the second an element of \( H \). The generalized traction \( \mathcal{E}\mathcal{E}u^0n \) on \( \partial D \) is introduced as an element of \( H^{-1/2}(\partial D)^2 \). For this case we have suitable integration by parts formulas given by the following two lemmas.

Lemma 3.3. Since \( \bar{u}^0 \) belongs to \( H^1(D, \mathbb{R}^2)' \) and \( u^0 \) is in \( SBD^2(D) \) then the generalized traction \( \mathcal{E}\mathcal{E}u^0n \) is uniquely defined as an element of \( H^{-1/2}(\partial D)^2 \) on the boundary \( \partial D \) is given by

\[
\langle \mathcal{E}\mathcal{E}u^0n, \gamma w \rangle = \int_D \mathcal{E}\mathcal{E}u^0 : \mathcal{E}w dx + \rho(\bar{u}^0, w),
\]

for all test functions \( w \) in \( H^1(D, \mathbb{R}^2) \) is uniquely defined.
Lemma 3.4. Since $\mathbf{u}_0^0(t)$ belongs to $W^\pm(D_\beta(\tau))'$ for a.e., $t \in (\tau, T)$ and $\mathbf{u}_0^0(t)$ is in $\text{SBD}^2(D)$ the generalized tractions $\mathcal{C}\mathbf{E}\mathbf{u}_0^0(t) \mathbf{n}^\pm$ are uniquely defined as elements of $H^{-1/2}(\partial D^\pm_\beta(\tau))^2$ on the upper and lower sides of the crack $\Gamma$ by

$$\langle \mathcal{C}\mathbf{E}\mathbf{u}_0^0(t) \mathbf{n}^\pm, \gamma \mathbf{w} \rangle = \int_{L^2_\beta(\tau)} \mathcal{C}\mathbf{E}\mathbf{u}_0^0(t) : \mathbf{E}\mathbf{w} \, dx + \rho(\mathbf{u}_0^0(t), \mathbf{w}),$$

for all test functions $\mathbf{w}$ in $W^\pm(D_\beta(\tau))$ and a.e., $t \in (\tau, T)$.

Lemmas 3.2 and 3.4 are proved in section 6.

The global dynamics for $\mathbf{u}_0(x, t)$ is given by the following theorem.

Theorem 3.3. The limit displacement field $\mathbf{u}_0^0$ satisfies

$$\rho \ddot{\mathbf{u}}_0^0 = \text{div} \left( \mathcal{C}\mathbf{E}\mathbf{u}_0^0 \right)$$

as elements of $H^{-1}(D, \mathbb{R}^2)$, for a.e., $t \in (0, T)$ and

$$\mathcal{C}\mathbf{E}\mathbf{u}_0^0 \mathbf{n} = \mathbf{g} \text{ on } \partial D,$$

where the traction $\mathbf{g}$ is given by (2.10) and equality holds as elements of $H^{-1/2}(\partial D)^2$ for a.e., $t \in (0, T)$. Moreover there is zero traction on the upper and lower sides of the crack $\Gamma$, $\tau \in (0, T)$, this is given by

$$\mathcal{C}\mathbf{E}\mathbf{u}_0^0(t) \mathbf{n}^\pm = 0, \text{ for } \{t(0) < x_1 < t(\tau) - \beta; x_2 = 0\}$$

as elements of $H^{-1/2}(\partial D^\pm_\beta(\tau))^2$ for a.e., $t \in (\tau, T)$, for all $\beta \in (0, t(\tau) - t(0))$.

Here the normal tractions (3.25) and (3.26) are defined in the generalized sense (3.22), (3.23) respectively. To summarize theorem 3.3 delivers the global description of the displacement fields inside the cracking body. Together they deliver the elastodynamic equations and homogeneous traction boundary conditions on the crack faces given in LEFM [14, 27, 2], and [33].

The field $\mathbf{u}_0(t, x)$ is seen to be a weak solution of the wave equation on $D_t$ for $t \in [0, T]$. We begin with the definition of weak solution of the wave equation on time dependent domains introduced in [10]. Neumann boundary conditions are considered and the space $H^1(D_t, \mathbb{R}^2) = H^1(D_t, \mathbb{R}^2) \cap L^2(D_t, \mathbb{R}^2)$ is introduced. Set $V_t = H^1(D_t, \mathbb{R}^2)$, $V^*_t = H^1(D_t, \mathbb{R}^2)'$ for $t \in [0, T]$, and $H = L^2(D, \mathbb{R}^2)$. Recall $\Gamma_s \subset \Gamma_t$ when $0 \leq s \leq t \leq T$ and $H^1(\Gamma_t) < a - \ell(0)$.

Definition 3.1. [10] $V$ is the space of functions $\mathbf{v} \in L^2(0, T; V_T) \cap H^1(0, T; H)$ such that $\mathbf{v}(t) \in V_t$ for a.e. $t \in (0, T)$. It is a Hilbert space with scalar product given by

$$(\mathbf{u}, \mathbf{v})_V = (\mathbf{u}, \mathbf{v})_{L^2(0, T; V_T)} + (\mathbf{u}, \mathbf{v})_{L^2(0, T; H)},$$

where $\mathbf{u}$ and $\mathbf{v}$ denote distributional derivatives with respect to $t$. 

Figure 4: Single-edge-notch and crack corresponding to $\epsilon = 0$ limit.
\[ \ell_0(t) - \beta \]

Figure 5: Domain \( L^+_\beta(t) \) adjacent to \( \partial D^+_\beta(t) \). The boundary of \( L^+_\beta(t) \) interior to \( D^\beta(t) \) is denoted by the dashed line.

**Definition 3.2.** [10] Given \( g(t) \) defined by (2.10) the displacement \( u \) is said to be a weak solution of the wave equation

\[
\begin{aligned}
\rho \ddot{u}(t) + \text{div}(C \varepsilon u(t)) &= 0 \\
C \varepsilon u(t) n &= g(t), \text{ on } \partial D \\
u(t) &\in V_t
\end{aligned}
\] (3.28)

on the time interval \([0, T]\) if \( u \in V \) and

\[
- \int_0^T \rho \int_D \dot{u}(t) \cdot \dot{\varphi}(t) \, dx \, dt + \int_0^T \int_D C \varepsilon u(t) : \varepsilon \varphi(t) \, dx \, dt = \int_0^T \int_{\partial D} g(t) \cdot \varphi(t) \, d\sigma \, dt
\] (3.29)

for every \( \varphi \in V \) with \( \varphi(T) = \varphi(0) = 0 \).

**Theorem 3.4.** If the crack tip \( \ell^0(t) \) is continuous and strictly increasing for \( t \in [0, T] \) then the limit displacement \( u^0 \) is a weak solution of the wave equation on \( D_t \) for \( t \in [0, T] \) given by definition 3.2.

Theorem 3.4 establishes the link between the nonlocal theory and the theory of the wave equation on time dependent domains [10]. Here the choice of test functions delivers a variational description of vanishing normal traction for the solution of the weak formulation. If one assumes a more general crack structure for the nonlocal problem then a connection to the local problem for more general time dependent domains can be made, this is discussed in the conclusion.

4 Existence and uniqueness of nonlocal elastodynamics

We assert the existence and uniqueness for a solution \( u^e(x, t) \) of the nonlocal evolution with the balance of momentum given in strong form (2.15).

**Theorem 4.1. Existence and uniqueness of the nonlocal evolution.** The initial value problem given by (2.15) and (2.19) has a unique solution \( u(x, t) \) such that for every \( t \in [0, T] \), \( u \) takes values in \( L^2(D; \mathbb{R}^2) \) and belongs to the space \( C^2([0, T]; L^2(D; \mathbb{R}^2)) \).

The proof of this proposition follows from the Lipschitz continuity of \( L^e(u^e)(x, t) + b(x, t) \) as a function of \( u^e \) with respect to the \( L^2(D; \mathbb{R}^2) \) norm and the Banach fixed point theorem, see e.g. [20]. It is pointed out that \( SZ^e \) describes an unstable phase of the material however because the peridynamic force is a uniformly Lipschitz function on \( L^2(D; \mathbb{R}^2) \) the model can be viewed as an ODE for vectors in \( L^2(D; \mathbb{R}^2) \) and is well posed.

5 Symmetry of the limiting elastic displacement field

In this section theorem 5.1 is established. To prove theorem 5.1 the following lemma is used.
Lemma 5.1.

\[
\lim_{\epsilon_n \to 0} \frac{1}{\epsilon_n^2 \omega_2} \int_D \int_{\mathcal{H}_n(x) \cap D} \frac{|y - x|}{\epsilon_n} J^{\epsilon_n}(|y - x|) S(y, x, u^{\epsilon_n}(t))^{-} dy \varphi(x) dx
\]
\[
= \int_D \hbox{div} u^0(x, t) \varphi(x) dx
\]
\[
= \lim_{\epsilon_n \to 0} \frac{1}{\epsilon_n^2 \omega_2} \int_{\mathcal{S}^n} \int_{\mathcal{H}_n(x) \cap D} \frac{|y - x|}{\epsilon_n} J^{\epsilon_n}(|y - x|) S(y, x, u^{\epsilon_n}(t))^{+} dy \varphi(x) dx
\]
\[
= C \int_{\mathcal{J}^0(t)} [u^0(x, t)] \cdot \mathbf{n} \varphi(x) d\mathcal{H}^1(x)
\]  

for all scalar test functions \( \varphi \) that are differentiable with support in \( D \). Here \([u^0(x, t)]\) denotes the jump in displacement across \( \mathcal{J}^0(t) \) and \( \mathbf{n} \) is the unit normal to \( \mathcal{J}^0(t) \) and points in the vertical direction \( e^2 \), and \( C = \omega_2 \int_0^1 r^2 dr \).

Proof of Lemma. It is convenient to make the change of variables \( y = x + \epsilon \xi \) where \( \xi \) belongs to the unit disk at the origin \( \mathcal{H}_1(0) = \{ ||\xi|| < 1 \} \) and \( e = \xi/||\xi|| \). The strain is written

\[
\frac{u^\epsilon(x + \epsilon \xi) - u^\epsilon(x)}{\epsilon} := D^\epsilon e \varphi, \quad \text{and}
\]
\[
S(y, x, u^\epsilon(t)) = D^\epsilon e u^\epsilon \cdot e,
\]
and for infinitely differentiable scalar valued functions \( \varphi \) and vector valued functions \( w \) bounded and continuous on \( D \) we have

\[
\lim_{\epsilon \to 0} D^\epsilon e \varphi = -\nabla \varphi \cdot e,
\]
and

\[
\lim_{\epsilon \to 0} D^\epsilon e w \cdot e = \mathcal{E} w \cdot e
\]

where the convergence is uniform in \( D \). We now recall \( S(y, x, u^\epsilon(t))^{-} = D^\epsilon e u^\epsilon \cdot e \) defined by (2.20). We extend \( D^\epsilon e u^\epsilon \cdot e \) by zero when \( x \in D \) and \( x + \epsilon \xi \notin D \) and

\[
\frac{1}{\epsilon_n^2 \omega_2} \int_D \int_{\mathcal{H}_n(x) \cap D} \frac{|y - x|}{\epsilon_n} J^{\epsilon_n}(|y - x|) S(y, x, u^{\epsilon_n}(t))^{-} |^2 dy dx
\]
\[
= \int_{D \times \mathcal{H}_1(0)} ||\xi|| J(||\xi||) (D^\epsilon e ||\xi|| u^{\epsilon_n} \cdot e)^{-} |^2 d\xi dx.
\]

Then as in inequality (6.73) of [19] we have that

\[
\int_{D \times \mathcal{H}_1(0)} ||\xi|| J(||\xi||) (D^\epsilon e ||\xi|| u^{\epsilon_n} \cdot e)^{-} |^2 d\xi dx < C,
\]

for all \( \epsilon_n > 0 \). From this we can conclude there exists a function \( g(x, \xi) \) such that a subsequence

\[
D^\epsilon e ||\xi|| u^{\epsilon_n} \cdot e \to g(x, \xi)
\]

converges weakly in \( L^2(D \times \mathcal{H}_1(0), \mathbb{R}) \) where the \( L^2 \) norm and inner product are with respect to the weighted measure \( ||\xi|| J(||\xi||) d\xi dx \). Now for any positive number \( \eta \) and any subset \( D' \) compactly contained in \( D \) we can argue as in (19) proof of lemma 6.6) that \( g(x, \xi) = \mathcal{E} u^0 e \cdot e \) for all points in \( D' \) with \( \text{dist}(D', \partial D) > \eta \). Since \( D' \) and \( \eta \) is arbitrary we get that

\[
g(x, \xi) = \mathcal{E} u^0 e \cdot e
\]
almost everywhere in $D$. Additionally for any smooth scalar test function $\varphi(x)$ with compact support in $D$ straight forward computation gives

$$\lim_{\epsilon_n \to 0} \int_{D \times H_1(0)} |\xi| J(|\xi|) D_e^{\epsilon_n} |\xi| u^{\epsilon_n} \cdot e \, d\xi \varphi(x) \, dx$$

$$= \int_{D \times H_1(0)} |\xi| J(|\xi|) g(x, \xi) \, d\xi \varphi(x) \, dx$$

$$= \int_{D \times H_1(0)} |\xi| J(|\xi|) E u^0(x) e \cdot e \, d\xi \varphi(x) \, dx$$

$$= C \int_D \text{div} u^0(x) \varphi(x) \, dx,$$

Here $C = \omega_2 \int_0^1 r^2 J(r) \, dr$ and we have used

$$\frac{1}{\omega_2} \int_{H_1(0)} |\xi| J(|\xi|) e_i e_j \, d\xi = \delta_{ij} \int_0^1 r^2 J(r) \, dr. \quad (5.10)$$

On the other hand for any smooth test function $\varphi$ with compact support in $D$ we can integrate by parts and use (5.3) to write

$$\lim_{\epsilon_n \to 0} \int_{D \times H_1(0)} |\xi| J(|\xi|) D_e^{\epsilon_n} |\xi| u^{\epsilon_n} \cdot e \varphi(x) \, d\xi \, dx$$

$$= \lim_{\epsilon_n \to 0} \int_{D \times H_1(0)} |\xi| J(|\xi|) D_e^{\epsilon_n} |\xi| \varphi(x) u^{\epsilon_n} \cdot e, \, d\xi \, dx$$

$$= \int_{D \times H_1(0)} |\xi| J(|\xi|) u^0 \cdot e \nabla \varphi(x) \cdot e \, d\xi \, dx$$

$$= -C \int_D u^0 \cdot \nabla \varphi(x) \, dx$$

$$= C \int_D \text{tr} E u^0 \varphi(x) \, dx,$$

where $E u^0$ is the strain of the $SBD^2$ limit displacement $u^0$. Now since $u^0$ is in $SBD$ its weak derivative satisfies (5.11) and it follows on choosing $\Phi_{ij} = \delta_{ij} \varphi$ that

$$\int_D \text{tr} E u^0 \varphi \, dx = \int_D \text{div} u^0 \varphi \, dx + \int_{J_{\omega^0(1)}} [u^0] \cdot n \varphi \, dH^1(x), \quad (5.12)$$

and

$$\int_{D \times H_1(0)} |\xi| J(|\xi|) D_e^{\epsilon_n} |\xi| u^{\epsilon_n} \cdot e \, d\xi \varphi(x) \, dx$$

$$= \int_{D \times H_1(0)} |\xi| J(|\xi|) (D_e^{\epsilon_n} |\xi| u^{\epsilon_n} \cdot e)^- \, d\xi \varphi(x) \, dx$$

$$+ \int_{D \times H_1(0)} |\xi| J(|\xi|) (D_e^{\epsilon_n} |\xi| u^{\epsilon_n} \cdot e)^+ \, d\xi \varphi(x) \, dx$$

(5.13)

to conclude

$$\lim_{\epsilon_n \to 0} \int_{D \times H_1(0)} |\xi| J(|\xi|) (D_e^{\epsilon_n} |\xi| u^{\epsilon_n} \cdot e)^+ \, d\xi \varphi(x) \, dx$$

$$= C \int_{J_{\omega^0(1)}} [u^0] \cdot n \varphi \, dH^1(x). \quad (5.14)$$
On changing variables we obtain the identities:

\[
\lim_{\varepsilon_n \to 0} \frac{1}{\varepsilon_n^2} \int_D \int_{\mathcal{H}_n(x)} \frac{|y - x|}{\varepsilon_n} f^\varepsilon_n(|y - x|) S(y, x, u^{\varepsilon_n}(t))^+ \, dy \varphi(x) \, dx = C \int_{\mathcal{J}_{u^\varepsilon}(t)} [u^\varepsilon] \cdot n \, d\mathcal{H}^1(x).
\]

and

\[
\lim_{\varepsilon_n \to 0} \frac{1}{\varepsilon_n^2} \int_D \int_{\mathcal{H}_n(x)} \frac{|y - x|}{\varepsilon_n} f^\varepsilon_n(|y - x|) S(y, x, u^{\varepsilon_n}(t))^+ \, dy \varphi(x) \, dx = C \int_D \text{div} u^{\varepsilon}(x) \varphi(x) \, dx,
\]

and lemma [6.1] is proved.

To prove theorem [6.1] note first that the sequence \( \{u^\varepsilon\}_{\varepsilon>0} \) converges in \( L^2(D, \mathbb{R}^2) \) to \( u^0 \) and \( u^0 \) is in \( SBD^2(D) \). On passage to a subsequence if necessary it is seen that \( \{u^\varepsilon\}_{\varepsilon>0} \) converges almost everywhere to \( u^0 \). Since the subsequence \( u^\varepsilon_1 \) is even with respect to \( x_2 = 0 \) it is evident from (3.8) that \( u^0_1 \) is odd, a.e. with respect to two dimensional Lebesgue measure and from (3.9) does not jump across the \( x_2 = 0 \) axis. Similarly since the subsequence \( u^\varepsilon_2 \) is odd we find that \( u^0_2 \) is odd a.e. with respect to two dimensional Lebesgue measure. From (2.28) and lemma [5.1] the jump set \( \mathcal{J}_{u^\varepsilon} \) does not intersect \( \{\ell^0 < x_1 < a, x_2 = 0\} \). It now follows from (3.9) and (6.10) that \( u^0_1 = 0 \) a.e. with respect to one dimensional \( \mathcal{H}^1 \) measure or equivalently Lebesgue measure on \( \{\ell^0 < x_1 < a, x_2 = 0\} \) and the theorem is established.

### 6 Convergence of nonlocal elastodynamics

In this section we give the proofs of lemmas [3.1] [3.2] [3.3] [3.4] and theorems [3.2] and [3.3]. We begin with the derivation of theorem [3.3]. This is done with the aid of the following variational identities over properly chosen test spaces. The first variational identity over the domain \( D \) is given in the following lemma.

**Lemma 6.1.** For a.e. \( t \in (0, T) \) we have

\[
\rho'(u^0, w) = -\int_D C\mathcal{E}u^0 : \mathcal{E}w \, dx + \int_{\partial D} g \cdot w \, d\sigma, \quad \text{for all} \ w \in \mathring{H}^1(D, \mathbb{R}^2),
\]

where \( \langle \cdot, \cdot \rangle \) is the duality paring between \( \mathring{H}^1(D, \mathbb{R}^2) \) and its Hilbert space dual \( \mathring{H}^1(D, \mathbb{R}^2)' \).

The next variational identity applies to the domains \( L^\pm_\beta(t) \) adjacent to the moving crack.

**Lemma 6.2.** The field \( u^0(t) \) is a bounded linear functional on the spaces \( W^\pm(D_\beta(t)) \) for a.e. \( t \in (\tau, T) \) and we have

\[
\rho'(u^0, w) = -\int_{L^\pm_\beta(\tau)} C\mathcal{E}u^0 : \mathcal{E}w \, dx + \int_{\partial D^\pm_\beta(\tau)} g \cdot w \, d\sigma, \quad \text{for all} \ w \in W^\pm(D_\beta(\tau)).
\]

We now prove theorem [3.3] using lemmas [3.3] and [6.1] and the variational identities given above by Lemmas [6.1] and [6.2]. We may choose test functions \( w \) in \( H^1_0(D, \mathbb{R}^2) \subset \mathring{H}^1(D, \mathbb{R}^2) \) in (6.1) to see that

\[
\rho u^0_\tau = \text{div} (C\mathcal{E}u^0)
\]

as elements of \( H^{-1}(D, \mathbb{R}^2) \) and (3.24) of theorem [3.3] is established. The traction on \( \partial D \) given by (3.23) now follows immediately from lemma [3.3] and lemma [6.1]. Similarly the zero traction force
acting on the component of $\partial D_\beta(\tau)\pm$ lying on the crack faces given by (3.26) now follows immediately from lemma 3.3 and lemma 6.2. This concludes the proof of theorem 6.3.

Lemmas 3.3 and 5.4 will be shown to follow from a generalized trace formula on the boundary of a Lipschitz domain $\Omega$. We call the domain $\Omega$ a polygon when it is a Lipschitz domain with smooth curvilinear arcs for edges $E_i$, $i = 1, \ldots, M$, connected by vertices. We introduce the Sobolev space defined on $\Omega$ given by

$$H^{1,0}(\Omega, \mathbb{R}^2) = \{ w \in H^1(\Omega, \mathbb{R}^2) \text{ and } \gamma w = 0 \text{ on a subset of edges} \},$$

(6.4)

here $H^{1,0}(\Omega, \mathbb{R}^2) \subset H^1(\Omega, \mathbb{R}^2)$.

**Lemma 6.3.** Given a domain $\Omega$ with Lipschitz boundary and let $u^0$ be an element of $SBV^2(\Omega)$, let $f$ be an element of $H^1(\hat{\Omega}, \mathbb{R}^2)'$, and

$$\text{div} (C \mathcal{E} u^0) = f$$

(6.5)

as elements of $H^{-1}(\Omega, \mathbb{R}^2)$. Suppose first that test functions $w$ belong to $\hat{H}^1(\Omega, \mathbb{R}^2)$ and define $C \mathcal{E} u^0 n$ on $\partial \Omega$ by

$$\langle C \mathcal{E} u^0 n, \gamma w \rangle = \int_{\Omega} C \mathcal{E} u^0 : E w \, dx + \langle f, w \rangle$$

(6.6)

for all $w$ in $\hat{H}^1(\Omega, \mathbb{R}^2)$. Then the functional $\langle C \mathcal{E} u^0 n, \gamma w \rangle$ is uniquely defined for all test functions $\gamma$ in $\hat{H}^1(\Omega, \mathbb{R}^2)$, hence $C \mathcal{E} u^0 n$ belongs to $H^{-1/2}(\partial \Omega)$.

Next suppose $\Omega$ is a polygon. Let $w$ belong to $H^{1,0}(\Omega, \mathbb{R}^2)$ and let $f$ be an element of $H^{1,0}(\Omega, \mathbb{R}^2)'$ and let $\text{div} (C \mathcal{E} u^0)$ and $f$ satisfy (6.5) as elements of $H^{-1}(\Omega, \mathbb{R}^2)$. Define $C \mathcal{E} u^0 n$ on $\partial \Omega$ by

$$\langle C \mathcal{E} u^0 n, \gamma w \rangle = \int_{\Omega} C \mathcal{E} u^0 : E w \, dx + \langle f, w \rangle$$

(6.7)

for all $w$ in $H^{1,0}(\Omega, \mathbb{R}^2)$, the functional $\langle C \mathcal{E} u^0 n, \gamma w \rangle$ is uniquely defined for all test functions $\gamma$ in $H^{1,0}(\Omega, \mathbb{R}^2)$, hence $C \mathcal{E} u^0 n$ belongs to the dual space $H^{1/2}_{d0}(\partial \Omega)$.

We now prove lemmas 3.3 and 3.4. With the hypothesis of lemma 3.3 we apply lemma 6.1 with test functions $w$ in $H^1(D, \mathbb{R}^2) \subset H^1(D, \mathbb{R}^2)$ in (6.11) to see as before

$$\rho u^0 = \text{div} (C \mathcal{E} u^0),$$

(6.8)

as elements of $H^{-1}(\Omega, \mathbb{R}^2)$. Then we set $f = \rho u^0$ and lemma 3.3 follows immediately from the first part of lemma 6.3. Now we see that the domains $L^\pm_\beta(t)$ of lemma 3.4 are polygons. With the hypothesis of lemma 3.4 we apply lemma 6.2 and first consider test functions $w$ in $W^\pm(D_\beta(t))$ that vanish on the boundary of $L^\pm_\beta(t)$. Substitution into (6.2) gives

$$\rho u^0 = \text{div} (C \mathcal{E} u^0),$$

(6.9)

as elements of $H^{-1}(L^\pm_\beta(t), \mathbb{R}^2)$. Note that $w \in W^\pm(D_\beta(t))$ implies that the restriction of $w$ to $L^\pm_\beta(t)$ belongs to

$$H^{1,0}(L^\pm_\beta(t), \mathbb{R}^2) = \{ w \in H^1(L^\pm_\beta(t), \mathbb{R}^2) \text{ and } \gamma w = 0 \text{ on } \partial L^\pm_\beta \},$$

(6.10)

so we set $f = \rho u^0$ and lemma 3.4 follows immediately from the second part of lemma 6.3.

We now prove the lemmas introduced in this section. We begin with the proof of lemma 6.3 following [23]. To fix ideas we prove the second part of lemma 6.2 noting the first part follows identical lines. First note if $u^0$ belongs to $SBV^2(\Omega)$, then $\int_{\Omega} C \mathcal{E} u^0 : E w \, dx$ as a map from $w \in H^{1,0}(\Omega, \mathbb{R}^2)$ to $\mathbb{R}$ belongs to $H^{1,0}(\Omega, \mathbb{R}^2)'$. Second note that the trace operator mapping $H^{1,0}(\Omega, \mathbb{R}^2)$ to $H^{1,0}_{d0}(\Omega)$ has a continuous right inverse denoted by $\tau$. We define $\tilde{g}$ by

$$\langle \tilde{g}, v \rangle = \int_{\Omega} C \mathcal{E} u^0 : E \tau v \, dx + \langle f, \tau v \rangle$$

(6.11)
for all $v$ in $H^{0,1/2}(\partial \Omega)$ to show

$$\langle \tilde{g}, \gamma w \rangle = \int_{\Omega} \mathbb{C} \mathcal{E} u^0 : \mathcal{E} w \ dx + \langle f, w \rangle$$  \hspace{1cm} (6.12)$$

for all $w$ in $H^{1,0}(\Omega, \mathbb{R}^2)$. To see this pick $w$ in $H^{1,0}(\Omega, \mathbb{R}^2)$ and set $w_0 = w - \tau \gamma w$ so $w_0$ is in $H^{1,0}(\Omega, \mathbb{R}^2)$ and from (6.10) we have

$$- \int_{\Omega} \mathbb{C} \mathcal{E} u^0 : \mathcal{E} w_0 \ dx = \langle w_0, f \rangle,$$  \hspace{1cm} (6.13)$$

so

$$- \int_{\Omega} \mathbb{C} \mathcal{E} u^0 : \mathcal{E} w \ dx + \int_{\Omega} \mathbb{C} \mathcal{E} u^0 : \mathcal{E} \tau \gamma w \ dx = \langle \tau \gamma w, f \rangle - \langle \tau \gamma w, f \rangle.$$  \hspace{1cm} (6.14)$$

Equation (6.12) follows directly from (6.14), (6.11), and manipulation. Now we show that the definition of $\tilde{g}$ given by (6.11) is unique and independent of the choice of right inverse (lift) $\tau$. Suppose we have $g^*$ defined by the lift $\tau^*$ given by

$$\langle g^*, v \rangle = \int_{\Omega} \mathbb{C} \mathcal{E} u^0 : \mathcal{E} \tau^* v \ dx + \langle f, \tau^* v \rangle$$  \hspace{1cm} (6.15)$$

for all $v$ in $H^{0,1/2}(\partial \Omega)$. From (6.12) and linearity we get

$$\langle \tilde{g} - g^*, \gamma w \rangle = 0,$$  \hspace{1cm} (6.16)$$

for all $w$ in $H^{1,0}(\Omega, \mathbb{R}^2)$ and uniqueness follows. We define $\mathbb{C} \mathcal{E} u^0 n = \tilde{g}$ and the second part of lemma (6.3) is proved.

Next we give the proof of lemma (3.1). First we show that the sequence $\{b^\epsilon(t)\}$ is uniformly bounded in $H^1(D, \mathbb{R}^2)'$ for $t \in [0, T]$. Let $\chi^\epsilon = \chi^\epsilon_+ + \chi^\epsilon_-$ where $\chi^\epsilon_\pm$ are the indicator functions of the body force layers defined in (2.9) so recalling (2.10) we have for any $w \in H^1(D, \mathbb{R}^2)$,

$$\int_D b^\epsilon(x, t) \cdot w(x) \ dx = \int_D \frac{1}{\epsilon_n} \chi^\epsilon(x) g(x_1, t) \cdot w(x) \ dx$$

$$= \int_D \frac{1}{\sqrt{\epsilon_n}} \chi^\epsilon(x) g(x_1, t) \cdot \frac{1}{\sqrt{\epsilon_n}} \chi^\epsilon(x) w(x) \ dx$$

$$\le \left( \int_D \frac{1}{\epsilon_n} |g(t)|^2 \ dx \right)^{1/2} \left( \int_D \frac{1}{\epsilon_n} \chi^\epsilon(x) |w|^2 \ dx \right)^{1/2}$$

$$\le 2 \|g(t)\|_{L^2(\theta, a - \theta)} I_{\epsilon_n}.$$  \hspace{1cm} (6.17)$$

Here $I_{\epsilon_n}$ is given by

$$I_{\epsilon_n} = \left( \int_D \frac{1}{\epsilon_n} \chi^\epsilon(x) |w|^2 \ dx \right)^{1/2}$$

$$= \left( \int_0^1 \int_{\theta}^{a - \theta} |w(x_1, b/2 + \epsilon_n(y_2 - 1))|^2 \ dx_1 dy_2 \right)^{1/2}$$

$$\quad + \int_0^1 \int_{\theta}^{a - \theta} |w(x_1, b/2 + \epsilon_n(1 - y_2))|^2 \ dx_1 dy_2 \right)^{1/2}$$  \hspace{1cm} (6.18)$$

where the change of variables $x_2 = \pm b/2 \pm \epsilon_n \pm \epsilon_n y_2$ has been made. From the change of variable it is evident that the factor $I_{\epsilon_n}$ is bounded above by

$$I_{\epsilon_n} \le \left( \int_0^1 \int_{\partial D_{\Delta(y)}} |w|^2 \ ds \ dy \right)^{1/2}.$$  \hspace{1cm} (6.19)$$
where \( D_{\delta(y)} = \{ x \in D : \text{dist}(x, \partial D) > \delta(y) \} \) and \( \delta(y) = \epsilon_n(1 - y) \), for \( 0 < y < 1 \). Since the trace operator is a bounded linear transformation between \( H^1(D_{\delta(y)}, \mathbb{R}^2) \) and \( L^2(\partial D_{\delta(y)})^2 \) we have

\[
\int_{\partial D_{\delta(y)}} |u|^2 \, ds \leq C_{\delta(y)} \|u\|_{H^1(D_{\delta(y)}, \mathbb{R}^2)}^2 \leq C_{\delta(y)} \|u\|_{H^1(D, \mathbb{R}^2)}^2. \tag{6.20}
\]

Additionally \( C_{\delta(y)} \) depends only on the Lipschitz constant of the boundary \( \Gamma \) so for the case at hand we see that

\[
\sup_{y \in [0, 1]} \{ C_{\delta(y)} \} < \infty, \tag{6.21}
\]

and from \( 6.17, 6.19, \) and \( 6.21 \) we conclude that there is a constant \( C \) independent of \( t \) and \( \epsilon_n \) such that

\[
|\int_D b^n(x, t) \cdot w(x) \, dx| \leq C \|w\|_{H^1(D, \mathbb{R}^2)}^2, \tag{6.22}
\]

so

\[
\sup_{\epsilon_n > 0} \int_0^T \|b^n(t)\|_{H^1(D, \mathbb{R}^2)}^2 \, dt < \infty. \tag{6.23}
\]

Thus we can pass to a subsequence also denoted by \( \{b^n\}_{n=1}^{\infty} \) that converges weakly to \( b^0 \) in \( L^2(0, T; H^1(D; \mathbb{R}^2)^\prime) \). Next we identify the weak limit \( b^0(t) \) for a dense set of trial fields. Let \( w \in C^1(D, \mathbb{R}^2) \) then a change of variables \( x_2 = \pm \frac{b}{2} \pm \epsilon_n \pm \epsilon_n y_2 \) gives

\[
\int_D b^n(x, t) \cdot w(x) \, dx = \int_D \frac{1}{\epsilon_n} \chi(x) g(x_1, t) \cdot w(x) \, dx
\]

\[
= \int_0^1 \int_0^\theta g_+(x_1, t) e^2 \cdot w(x_1, \frac{b}{2} + \epsilon_n(y_2 - 1)) \, dx_1 \, dy_2 \tag{6.24}
\]

\[
+ \int_0^1 \int_0^\theta g_-(x_1, t) e^2 \cdot w(x_1, -\frac{b}{2} + \epsilon_n(1 - y_2)) \, dx_1 \, dy_2.
\]

One passes to the \( \epsilon_n \to 0 \) limit in \( 6.24 \) applying the uniform continuity of \( w \) to obtain

\[
\lim_{\epsilon_n \to 0} \int_D b^n(x, t) \cdot w(x) \, dx = \int_{\partial D} g \cdot w \, d\sigma. \tag{6.25}
\]

Lemma 3.1 now follows noting that \( C^1(D, \mathbb{R}^2) \) is dense in \( H^1(D, \mathbb{R}^2) \).

We now establish lemma 3.2 The strong convergence

\[
\mathbf{u}^n \to \mathbf{u}^0 \text{ strong in } C([0, T]; \dot{L}^2(D; \mathbb{R}^2)) \tag{6.26}
\]

follows immediately from the same arguments used to establish theorem 5.1 of \([19]\) . The weak convergence

\[
\dot{\mathbf{u}}^n \to \dot{\mathbf{u}}^0 \text{ weakly in } L^2(0, T; \dot{L}^2(D; \mathbb{R}^2)) \tag{6.27}
\]

follows noting that theorem 2.2 of \([19]\) shows that

\[
\sup_{\epsilon_n > 0} \int_0^T \|\dot{\mathbf{u}}^n(t)\|^2_{L^2(D; \mathbb{R}^2)} \, dt < \infty. \tag{6.28}
\]

Thus we can pass to a subsequence also denoted by \( \{\dot{\mathbf{u}}^n\}_{n=1}^{\infty} \) that converges weakly to \( \dot{\mathbf{u}}^0 \) in \( L^2(0, T; \dot{H}^1(D; \mathbb{R}^2)^\prime) \).

To prove

\[
\ddot{\mathbf{u}}^n \to \ddot{\mathbf{u}}^0 \text{ weakly in } L^2(0, T; \dot{H}^1(D; \mathbb{R}^2)^\prime) \tag{6.29}
\]

we must show that

\[
\sup_{\epsilon_n > 0} \int_0^T \|\ddot{\mathbf{u}}^n(t)\|^2_{H^1(D, \mathbb{R}^2)} \, dt < \infty, \tag{6.30}
\]
and existence of a weakly converging sequence follows. We multiply \([2.15]\) with a test function \(w\) from \(H^1(D; \mathbb{R}^2)\) and integrate over \(D\).

A straightforward integration by parts gives

\[
\int_D \ddot{u}^e(x, t) \cdot w(x) \, dx = -\frac{1}{\rho} \int_D \int_{H_n(x) \cap D} |y - x| \partial_3 W^n(S(y, x, u^n(t))) S(y, x, w) \, dy \, dx + \frac{1}{\rho} \int_D b^n(x, t) \cdot w(x) \, dx,
\]

and we now estimate the right hand side of \(6.31\). The first term on the righthand side is denoted by \(I^n\) and we change variables \(y = x + \epsilon \xi, |\xi| < 1,\), with \(dy = \epsilon^2 \, d\xi\) and write out \(\partial_3 W^n(S(y, x, u^n(t)))\) to get

\[
I^n = -\frac{1}{\rho \omega_2} \int_{D \times H_1(0) \cap A^-_n} \omega(x, \epsilon \xi) |\xi| \varepsilon_n^2 \left( \varepsilon_n |\xi| \|D_{\epsilon_n}^e |\xi| u^n \cdot e|^2 \right) d\xi \, dx + 2 \left( D_{\epsilon_n}^e |\xi| u^n \cdot e \right) \left( D_{\epsilon_n}^e |\xi| w \cdot e \right) d\xi \, dx,
\]

where \(\omega(x, \epsilon \xi)\) is unity if \(x + \epsilon \xi\) is in \(D\) and zero otherwise. We define the sets

\[
A^-_n = \left\{ (x, \xi) \in D \times H_1(0); |D_{\epsilon_n}^e |\xi| u^n \cdot e| < \frac{\varepsilon^2}{\varepsilon_n |\xi|} \right\},
\]

\[
A^+_n = \left\{ (x, \xi) \in D \times H_1(0); |D_{\epsilon_n}^e |\xi| u^n \cdot e| \geq \frac{\varepsilon^2}{\varepsilon_n |\xi|} \right\},
\]

with \(D \times H_1(0) = A^-_n \cup A^+_n\) and we write

\[
I^n = I_1^n + I_2^n,
\]

where

\[
I_1^n = -\frac{1}{\rho \omega_2} \int_{D \times H_1(0) \cap A^-_n} \omega(x, \epsilon \xi) |\xi| \varepsilon_n^2 \left( \varepsilon_n |\xi| \|D_{\epsilon_n}^e |\xi| u^n \cdot e|^2 \right) d\xi \, dx + 2 \left( D_{\epsilon_n}^e |\xi| u^n \cdot e \right) \left( D_{\epsilon_n}^e |\xi| w \cdot e \right) d\xi \, dx,
\]

\[
I_2^n = -\frac{1}{\rho \omega_2} \int_{D \times H_1(0) \cap A^+_n} \omega(x, \epsilon \xi) |\xi| \varepsilon_n^2 \left( \varepsilon_n |\xi| \|D_{\epsilon_n}^e |\xi| u^n \cdot e|^2 \right) d\xi \, dx + 2 \left( D_{\epsilon_n}^e |\xi| u^n \cdot e \right) \left( D_{\epsilon_n}^e |\xi| w \cdot e \right) d\xi \, dx.
\]

In what follows we will denote positive constants independent of \(u^n\) and \(w \in H^1(D; \mathbb{R}^2)\) by \(C\).

First note that \(h\) is concave so \(h'(r)\) is monotone decreasing for \(r \geq 0\) and from Cauchy’s inequality, and \(56\) one has

\[
|I_1^n| \leq \frac{2h'(0) C}{\rho \omega_2} \left( \int_{D \times H_1(0) \cap A^-_n} \omega(x, \epsilon \xi) \|D_{\epsilon_n}^e |\xi| w \cdot e \|^2 d\xi \right)^{1/2} \leq \frac{2h'(0) C}{\rho \omega_2} \left( \int_{H(0)} \int_D \omega(x, \epsilon \xi) \|D_{\epsilon_n}^e |\xi| w \cdot e \|^2 dx d\xi \right)^{1/2}
\]

Since \(x\) and \(x + \epsilon \xi\) belong to \(D\) we write \(\xi = |\xi| e\) where \(e = \xi / |\xi|\) and calculation gives

\[
D_{\epsilon_n}^e |\xi| w \cdot e = \int_0^1 \EE w(x + s \epsilon_n |\xi| e) e \cdot e ds,
\]

(6.37)
with \( x + s_\epsilon \eta |e| e \in D \) for \( 0 < s < 1 \). Next introduce \( \chi_D(x + s_\epsilon \eta |e| e) \) taking the value 1, if \( x + s_\epsilon \eta |e| e \in D \) and 0 otherwise. Substitution of (6.37) into (6.30) and application of the Jensen inequality and Fubini’s theorem gives

\[
|I_1^n| \leq \frac{2h'(0)C}{\rho \omega_2} \left( \int_0^1 \int_{H(0)} \int_D \chi_D(x + s_\epsilon \eta |e| e) \| \xi w(x + s_\epsilon \eta |e| e) e \cdot e \|^2 \, dx \, d\xi \, ds \right)^{1/2}, \tag{6.38}
\]

and we conclude

\[
|I_1^n| \leq C \| w \|_{H^1(D; \mathbb{R}^2)}. \tag{6.39}
\]

Elementary calculation gives the estimate (see equation (6.53) of [19])

\[
\sup_{0 \leq x < \infty} |h'(\epsilon_n |x|^2) 2x| \leq \frac{2h'(\tau^2)\tau}{\sqrt{\epsilon_n |x|}}, \tag{6.40}
\]

and we also have (see equation (6.78) of [19])

\[
\int_{D \times H(0) \cap A^n_\tau} \omega(x, \epsilon_n \eta) J(|\xi|) \, d\xi \, dx < C \epsilon_n, \tag{6.41}
\]

so Cauchy’s inequality and the inequalities (6.37), (6.40), (6.41) give

\[
|I_2^n| \leq \frac{1}{\rho \omega_2} \int_{D \times H(0) \cap A^n_\tau} \omega(x, \epsilon_n \eta) \| J(|\xi|) \| \left( \frac{2h'(\tau^2)\tau}{\epsilon_n |\xi|} \right) \, d\xi \, dx,
\]

\[
\leq \frac{1}{\rho \omega_2} \left( \int_{D \times H(0) \cap A^n_\tau} \omega(x, \epsilon_n \eta) \| J(|\xi|) \| \left( \frac{2h'(\tau^2)\tau}{\epsilon_n |\xi|} \right) \, d\xi \, dx \right)^{1/2} \times \left( \int_{D \times H(0) \cap A^n_\tau} \omega(x, \epsilon_n \eta) |\xi|^2 \| D_\tau^n \| \| w \cdot e \|^2 \, d\xi \, dx \, dt \right)^{1/2}, \tag{6.42}
\]

\[
\leq C \| w \|_{H^1(D; \mathbb{R}^2)},
\]

and we conclude that the first term on the right hand side of (6.31) admits the estimate

\[
|I^n| \leq |I_1^n| + |I_2^n| \leq C \| w \|_{H^1(D; \mathbb{R}^2)}, \tag{6.43}
\]

for all \( w \in H^1(D; \mathbb{R}^2) \).

It follows immediately from lemma 3.1 that the second term on the right hand side of (6.31) satisfies the estimate

\[
\frac{1}{\rho} \left| \int_D b^n(x, t) \cdot w(x) \, dx \right| \leq C \| w \|_{H^1(D; \mathbb{R}^2)}, \text{ for all } w \in H^1(D; \mathbb{R}^2) \tag{6.44}
\]

From (6.43) and (6.44) we conclude that there exists a \( C > 0 \) so that

\[
\left| \int_D \tilde{u}^{\tau^n}(x, t) \cdot w(x) \, dx \right| \leq C \| w \|_{H^1(D; \mathbb{R}^2)}, \text{ for all } w \in \dot{H}^1(D; \mathbb{R}^2) \tag{6.45}
\]

so

\[
\sup_{\epsilon_n > 0} \sup_{t \in [0, T]} \left| \int_D \tilde{u}^{\tau^n}(x, t) \cdot w(x) \, dx \right| \| w \|_{H^1(D; \mathbb{R}^2)} < C, \text{ for all } w \in \dot{H}^1(D; \mathbb{R}^2), \tag{6.46}
\]

or

\[
\sup_{t \in [0, T]} \| \tilde{u}^{\tau^n}(t) \|_{H^1(D; \mathbb{R}^2)} < C, \text{ for all } \epsilon_n \tag{6.47}
\]

and (6.30) follows. The estimate (6.30) implies weak compactness and passing to subsequences if necessary we deduce that \( \tilde{u}^{\tau^n} \rightharpoonup \tilde{u}^0 \) weakly in \( L^2(0, T; \dot{H}^1(D; \mathbb{R}^2)) \) and lemma 3.2 is proved.
To establish Lemma 6.1 we take a test function \( \varphi(t)w(x) \) with \( \varphi \in C_c^\infty(0, T) \) and \( w \) in \( C^\infty(D, \mathbb{R}^2) \) orthogonal to rigid body motions. Substituting this test function into (2.14) and integration by parts in time gives

\[
\int_0^T \varphi(t) \int_D \dot{u}^\alpha(x, t) \cdot w(x) \, dx \, dt \\
= - \int_0^T \varphi(t) \int_D \int_{H_n(x) \cap D} |y - x| \partial_S W^\alpha(S(y, x, u^\alpha(t))) S(y, x, w) \, dy \, dx \, dt \\
+ \int_0^T \varphi(t) \int_D \dot{b}^\alpha(x, t) \cdot w(x) \, dx \, dt,
\]

The goal is to pass to the \( \epsilon_n = 0 \) limit in this equation to recover (6.1). The limit of the left hand side of (6.48) follows from Lemma 3.2

\[
\lim_{\epsilon_n \to 0} \int_0^T \varphi(t) \int_D \dot{u}^\alpha(x, t) \cdot w(x) \, dx \, dt = \int_0^T \varphi(t) \rho(\dot{u}^0(t), w) \, dt.
\]

To recover the \( \epsilon_n = 0 \) limit of the first term on the right hand side of (6.48) we appeal to the bound (6.43) to pass to the limit under the time integral using Lebesgue dominated convergence. Next apply Lemma 6.5 of [19] with straightforward modifications to get

\[
\lim_{\epsilon_n \to 0} I^{\epsilon_n} = - \lim_{\epsilon_n \to 0} \int_D \int_{H_n(x) \cap D} |y - x| \partial_S W^\alpha(S(y, x, u^\alpha(t))) S(y, x, w) \, dy \, dx \\
= - \lim_{\epsilon_n \to 0} \frac{2}{\omega_2} \int_{D \times H_1(0)} \omega(x, \epsilon_n \xi) ||J(\xi)|| h'(0)(D_{\epsilon}^{\alpha}[\xi] u^\alpha \cdot e) - (D_{\epsilon}^{\alpha}[\xi] w \cdot e) \, d\xi \, dx,
\]

where \( S(y, x, u^\alpha(t)) = (D_{\epsilon}^{\alpha}[\xi] u^\alpha \cdot e)^{-} \). As indicated in section 5 \( D_{\epsilon}^{\alpha}[\xi] u^\alpha \cdot e^{-} \to g(x, \xi) \) converges weakly in \( L^2(D \times H_1(0), \mathbb{R}^2) \) with respect to the measure \( ||J(\xi)|| d\xi \) and \( D_{\epsilon}^{\alpha}[\xi] w \cdot e \to \mathcal{E} w e \cdot e \) uniformly on \( D \), so

\[
\lim_{\epsilon_n \to 0} I^{\epsilon_n} = \frac{2}{\omega_2} \int_{D \times H_1(0)} \omega(x, \epsilon_n \xi) ||J(\xi)|| h'(0) g(x, \xi) \mathcal{E} w e \cdot e \, d\xi \, dx,
\]

and from (5.3) \( g(x, \xi) = \mathcal{E} w^0 e \cdot e \) and we recover

\[
\lim_{\epsilon_n \to 0} I^{\epsilon_n} = - \int_D \mathcal{C} \mathcal{E} u^0 : \mathcal{E} w \, dx,
\]

so

\[
\lim_{\epsilon_n \to 0} \int_0^T \varphi(t) I^{\epsilon_n} \, dt = - \int_0^T \varphi(t) \int_D \mathcal{C} \mathcal{E} u^0 : \mathcal{E} w \, dx \, dt.
\]

We pass to the limit in the second term on the right hand side of (6.48) using lemma 3.1 to obtain

\[
\int_0^T \varphi(t) \rho(\dot{u}^0(t), w) \, dt = - \int_0^T \varphi(t) \left( \int_D \mathcal{C} \mathcal{E} u^0 : \mathcal{E} w \, dx + \int_{\partial D} g \cdot w \, d\sigma \right) \, dt.
\]

From the density of \( C^\infty(D, \mathbb{R}^2) \) in \( w \in \dot{H}^1(D, \mathbb{R}^2) \) we see that (6.54) holds for all \( w \in \dot{H}^1(D, \mathbb{R}^2) \) since \( 6.54 \) holds for all \( \varphi \in C_c^\infty(0, T) \) we recover (6.1).

We now establish theorem 3.2 to show that \( u^\alpha(x, t) \) is a bounded linear functional on the spaces \( W^\pm(D_\beta(\tau)) \) for a.e. \( \tau \in (\tau, T) \). We illustrate the proof for \( w \in W^+(D_\beta(\tau)) \) noting that identical steps hold for \( w \in W^-(D_\beta(\tau)) \). Pick \( \tau \in (0, T) \), suppose \( \tau < t \), multiply (2.15) by a trial \( w \in
\( W^+(D_\beta(t)) \) and integrating by parts over \( D \) to gives

\[
\rho \int_D \tilde{u}^\tau(x, t) \cdot w(x) \, dx
\]

\[
= - \int_D \int_{H_n(x) \cap D} |y - x| \partial_3 W^\tau(S(y, x, u^\tau(t))) S(y, x, w) \, dy \, dx
\]

\[
+ \int_D b^\tau(x, t) \cdot w(x) \, dx
\]

(6.55)

Now we show that \( \tilde{u}^\tau(t) \) is bounded in \( W^+(D_\beta(t))' \) uniformly for all \( t \in (\tau, T) \) and \( 0 < \epsilon_n < \beta/2 \). As before the first term on the right-hand side is denoted by \( I^\tau \) and we change variables \( y = x + \epsilon \xi \), \( |\xi| < 1 \), with \( dy = \epsilon_n^2 \, d\xi \) and write out \( \partial_3 W^\tau(S(y, x, u^\tau(t))) \) to get

\[
I^\tau = - \frac{1}{\omega_2} \int_{D \times H_1(0)} \omega(x, \epsilon_n \xi) |\xi| J(|\xi|) \, h'(\epsilon_n |\xi| |D_{u^\tau}^\tau| u^\tau \cdot e|^2) \times 2(D_{u^\tau}^\tau |u^\tau \cdot e|) \, d\xi \, dx,
\]

(6.56)

where \( \omega(x, \epsilon_n \xi) \) is unity if \( x + \epsilon_n \xi \) is in \( D \) and zero otherwise. Note that the boundary component of \( \partial D_\beta^\tau(t) \) given by \( \{ x \in D : \xi(0) \leq x_1 \leq \xi(0) - \beta, x_2 = 0 \} \) is a subset of the failure zone centerline \( C^\tau(t) \) so for \( x \) and \( y \) in \( FZ^\tau(t) \) we see that \( f^\tau(y, x) = 0 \) or equivalently

\[
h'(\epsilon_n |\xi| |D_{u^\tau}^\tau| u^\tau \cdot e|^2) \times 2(D_{u^\tau}^\tau |u^\tau \cdot e|) = 0
\]

(6.57)

for \( x \) and \( y \) in \( FZ^\tau(t) \). Then for for \( n \) large enough so that \( \xi(0) - \beta < \xi^\tau(t) \) and \( 0 < \epsilon_n < \beta/2 \) and for test functions \( w \in W^+(D_\beta(t)) \) the product

\[
\chi(x, x + \epsilon_n \xi) h'(\epsilon_n |\xi| |D_{u^\tau}^\tau| u^\tau \cdot e|^2) \times 2(D_{u^\tau}^\tau |u^\tau \cdot e|) = \chi(x, x + \epsilon_n \xi) h'(\epsilon_n |\xi| |D_{u^\tau}^\tau| u^\tau \cdot e|^2) \times 2(D_{u^\tau}^\tau |u^\tau \cdot e|)
\]

(6.58)

where

\[
\chi(x, x + \epsilon_n \xi) = \begin{cases} 0, & \text{if the points } x, x + \epsilon_n \xi \text{ are separated by } \{ 0 \leq x_1 \leq \xi(0) - \beta, x_2 = 0 \} \\ 1, & \text{otherwise.} \end{cases}
\]

(6.59)

(Here we say that \( x, x + \epsilon_n \xi \) are separated by \( \{ 0 \leq x_1 \leq \xi(0) - \beta, x_2 = 0 \} \) when it is impossible to connect these two points by a line segment without crossing \( \{ 0 \leq x_1 \leq \xi(0) - \beta, x_2 = 0 \} \).) Then \( I^\tau \) becomes

\[
I^\tau = - \frac{1}{\omega_2} \int_{D \times H_1(0)} \omega(x, \epsilon_n \xi) \chi(x, x + \epsilon_n \xi) |\xi| J(|\xi|) h'(\epsilon_n |\xi| |D_{u^\tau}^\tau| u^\tau \cdot e|^2) \times 2(D_{u^\tau}^\tau |u^\tau \cdot e|) \, d\xi \, dx.
\]

(6.60)

We can now bound (6.60) as in (6.39) and change the order of integration to arrive at the upper bound

\[
|I^\tau| \leq \frac{2h'(0)C}{\omega_2} \left( \int_{H_1(0)} \int_{D} \omega(x, \epsilon_n \xi) \chi(x, x + \epsilon_n \xi) |D_{u^\tau}^\tau| w \cdot e|^2 \, dx \, d\xi \right)^{1/2}
\]

(6.61)
We change to slicing variables and write \( x = y + re \), where \( e \) is on the unit circle and \( y \in \Pi_e \) where \( \Pi_e \) is the subspace perpendicular to \( e \) and \( r \in \mathbb{R} \). We set \( D^e_y = \{ r \in \mathbb{R} : y + re \in D_\beta(\tau) \} \) and \( D^e = \{ y \in \Pi_e : D^e_y \neq \emptyset \} \) so

\[
|I^{\epsilon_n}| \leq \frac{2h'(0)C}{\omega_2} \left( \int_{H_1(0)} \int_{D^e_Y} \int_{D^e_y} \chi(y + re, y + (r + \epsilon_n|\xi|)e) |D^e_{y}[\xi]| |w \cdot e|^2 dr dy d\xi \right)^{1/2}.
\] (6.62)

We use the fact that functions in Sobolev spaces are absolutely continuous for a.e. lines to write \( (\ref{6.37}) \) for \( w \in W^+(D_\beta(\tau)) \) and

\[
|I^{\epsilon_n}| \leq \frac{2h'(0)C}{\omega_2} \left( \int_{H_1(0)} \int_{0}^{1} \int_{D^e_Y} \int_{D^e_y} \chi(y + re, y + (r + \epsilon_n|\xi|)e) |\mathcal{E}(y + (r + \epsilon_n|\xi|)e)e \cdot e|^2 dr dy d\xi \right)^{1/2}.
\] (6.63)

where Jensen inequality and Fubini’s theorem have been applied in the last line. Introducing \( \chi_{D_\beta(\tau)}(x) = 1 \) if its argument lies in \( D_\beta(\tau) \) and zero otherwise, applying \( \chi(y + re, y + (r + \epsilon_n|\xi|)e) \leq \chi_{D_\beta(\tau)}(y + re) \chi_{D_\beta(\tau)}(y + (r + \epsilon_n|\xi|)e) \) and changing to original variables gives

\[
|I^{\epsilon_n}| \leq \frac{2h'(0)C}{\omega_2} \left( \int_{H_1(0)} \int_{0}^{1} \int_{D} \chi_{D_\beta(\tau)}(x) \chi_{D_\beta(\tau)}(x + s \epsilon_n|\xi|e) |\mathcal{E} w(x + s \epsilon_n|\xi|e)e \cdot e|^2 dx d\xi ds \right)^{1/2}.
\] (6.64)

From this we conclude

\[
|I^{\epsilon_n}| \leq C \|w\|_{H^1(D_\beta(\tau); \mathbb{R}^2)}.
\] (6.65)

Arguments identical to the proof of lemma 3.31 show that the sequence \( b^\epsilon_n \) is uniformly bounded in \( W^+(D_\beta(\tau))' \) for all \( \tau \in [0, T] \) and \( \epsilon_n > 0 \) and together with (6.65) one concludes

\[
\sup_{\tau \in [0, T]} \|\tilde{u}^\epsilon_n(t)\|_{W^+(D_\beta(\tau); \mathbb{R}^2)} < C, \text{ for } \beta/2 > \epsilon_n > 0.
\] (6.66)

Hence

\[
\int_\tau^T \|\tilde{u}^\epsilon_n(t)\|^2_{W^+(D_\beta(\tau); \mathbb{R}^2)} dt < \infty \text{ for } \beta/2 > \epsilon_n > 0,
\] (6.67)

and passing to a subsequence if necessary gives a \( v(t) \) in \( L^2(\tau, T; W^+(D_\beta(\tau))') \) such that \( \tilde{u}^\epsilon_n \rightharpoonup v \) weakly in \( L^2(\tau, T; W^+(D_\beta(\tau))') \).

We finish the proof by showing \( v = \tilde{u}^0_\tau \). To see this note \( u^\epsilon_n \in C^2([0, T]; L^2(D, \mathbb{R}^2)) \) and for \( \varphi \in C^\infty_c(\tau, T) \) and for \( w \in W^+(D_\beta(\tau)) \) we have

\[
\int_\tau^T \int_D \tilde{u}^\epsilon_n \cdot w \varphi(t) dt = - \int_\tau^T \int_D \tilde{u}^\epsilon_n \cdot w \varphi(t) dt.
\] (6.68)

Passing to the \( \epsilon_n = 0 \) limit using lemma 3.32 applied to the right hand side gives

\[
\int_\tau^T \langle v, w \rangle \varphi(t) dt = - \int_\tau^T \int_D \tilde{u}^0_\tau \cdot w \varphi(t) dx dt \text{, for all } w \in W^+(D_\beta(\tau))
\] (6.69)

and we deduce from (6.69) that \( v = \tilde{u}^0_\tau \) as elements of \( W^+(D_\beta(\tau))' \). Identical arguments show that \( \tilde{u}^0_\tau \in W^-(D_\beta(\tau))' \) and Theorem 3.32 is proved.
We now prove lemma 6.2. We illustrate the proof for \( w(x) \in W^+(D_\beta(\tau)) \) noting an identical proof holds for \( w \in W^-(D_\beta(\tau)) \). Pick \( \varphi(t) \in C_c^\infty(\tau, T) \) and \( w(x) \in W^+(D_\beta(\tau)) \) and substitute into (2.14) and an integration by parts in time gives

\[
\int_\tau^T \rho \int_D \tilde{u}^{e_n}(x, t) \cdot w(x) \, dx \, \varphi(t) \, dt \\
= - \int_\tau^T \int_D \int_{H_\alpha(x) \cap D} |y - x| \partial_\nu W^{e_n}(S(y, x, u^{e_n}(t))) S(y, x, w) \, dy \, dx \, \varphi(t) \, dt \\
+ \int_\tau^T \int_D b^{e_n}(x, t) \cdot w(x) \, dx \, \varphi(t) \, dt
\]  

(6.70)

The goal is to pass to the \( \epsilon_n = 0 \) limit in this equation to recover (6.2). The limit of the left hand side of (6.70) follows from Theorem 3.2 and an integration by parts in time gives

\[
\lim_{\epsilon_n \to 0} \int_\tau^T \varphi(t) \rho \int_D \tilde{u}^{e_n}(x, t) \cdot w(x) \, dx \, dt = \int_\tau^T \varphi(t) \rho (\tilde{u}^0(t), w) \, dt.
\]

(6.71)

The first term on the right hand side of (6.71) is written

\[
\int_\tau^T \varphi I^{e_n} \, dt.
\]

We can recover the \( \epsilon_n = 0 \) limit of the first term on the right hand side of (6.71) by appealing to the bound (6.68) to pass to the limit under the time integral using Lebesgue dominated convergence once we show that for every \( w \in W^+(D_\beta(\tau)) \) the bounded sequence \( \{I^{e_n}(t)\} \) has a limit for a.e. \( t \in (\tau, T) \). To see this we apply (6.68) to get that

\[
I^{e_n}(t) = - \int_D \int_{H_\alpha(x) \cap D} |y - x| \partial_\nu W^{e_n}(S(y, x, u^{e_n}(t))) S(y, x, w) \, dy \, dx \\
= - \frac{1}{\omega_2} \int_D \int_{H_1(0)} \omega(x, \epsilon_n \xi) \chi(x, x + \epsilon_n \xi) \xi J(|\xi|) h'(\epsilon_n |\xi| D_\epsilon^{e_n} \xi) u^{e_n} \cdot e^{-|\xi|^2} \\
\times 2(D_\epsilon^{e_n} \xi) u^{e_n} \cdot e^{-|\xi|^2}(D_\epsilon^{e_n} \xi) w \cdot e) \, d\xi \, dx.
\]

(6.73)

The integrand is the product of two factors (note \( \omega(x, \epsilon_n \xi) \chi(x, x + \epsilon_n \xi) = \omega(x, \epsilon_n \xi)^2 \chi(x, x + \epsilon_n \xi)^2 \) and we show that on passing to a subsequence if necessary the first factor

\[
\omega(x, \epsilon_n \xi) \chi(x, x + \epsilon_n \xi) h'(\epsilon_n |\xi| D_\epsilon^{e_n} \xi) u^{e_n} \cdot e^{-|\xi|^2} \times 2(D_\epsilon^{e_n} \xi) u^{e_n} \cdot e^{-|\xi|^2} \to 2 h'(0) g(x, \xi, t)
\]

(6.74)

weakly in \( L^2(D \times \mathcal{H}_1(0), \mathbb{R}) \) and the second factor

\[
\omega(x, \epsilon_n \xi) \chi(x, x + \epsilon_n \xi) D_\epsilon^{e_n} \xi \cdot e \to \mathcal{E} w(x) e \cdot e.
\]

(6.75)

strong in \( L^2(D \times \mathcal{H}_1(0), \mathbb{R}) \). Here as in section 5 the \( L^2 \) norm and inner product are with respect to the weighted measure \( |\xi| J(|\xi|) d\xi dx \). Hence for fixed \( t \) we conclude that for any cluster point of \( \{I^{e_n}(t)\} \) there is a subsequence

\[
\lim_{\epsilon_n' \to 0} I^{e_n'}(t) = - \int_D \int_{H_\alpha(0)} |\xi| J(|\xi|) 2 h'(0) g(x, \xi, t) \mathcal{E} w(x) e \cdot e \, d\xi \, dx
\]

\[
= - \int_D \int_{H_\alpha(0)} 2|\xi| J(|\xi|) h'(0)(\mathcal{E} u^0(t, x) e \cdot e)(\mathcal{E} w(x) e \cdot e) \, d\xi \, dx
\]

(6.76)

\[
= - \int_D \mathcal{C} \mathcal{E} u^0(t, x) : \mathcal{E} w(x) \, dx,
\]
where the second line follows from (5.8) and the third line follows from a calculation. One obtains the same limit for subsequences of all possible distinct cluster points of \( \{I^n(t)\} \) to conclude there is one cluster point and we have identified \( \lim_{\epsilon_n \to 0} I^n(t) \) for a.e. \( t \in (0, T) \).

To conclude the weak and strong convergences (7.7) and (7.8) are established. First note that \( h'(r) \) is monotone decreasing in \( r \) so \( h'(r) (\epsilon_n \| D_{\epsilon_n}^* \| \mathbf{w}_n \cdot \mathbf{e}^-) \leq h'(0) \) and from (5.0) \( D_{\epsilon_n}^* \mathbf{w}_n \cdot \mathbf{e}^- \) is bounded in \( L^2 (D \times H_1(0), \mathbb{R}) \) so the first factor is bounded in \( L^2 (D \times H_1(0), \mathbb{R}) \) uniformly in \( \epsilon_n \) and has a subsequence that converges weakly to a limit written \( K(x, \xi, t) \). Application of Lemma 6.5 of [19] and (5.7) allows us to identify \( K(x, \xi, t) = 2h'(0)g(x, \xi, t) \) where we have explicitly written the time dependence of \( g(x, \xi, t) \) and weak convergence is established. Next we form

\[
A^* = \frac{1}{\omega_2} \int_{D \times H_1(0)} \omega(x, \epsilon_n \xi) \chi(x, x + \epsilon_n \xi) \|J(\xi)\| (D_{\epsilon_n}^* \mathbf{w} \cdot \mathbf{e}) - \mathcal{E} \mathbf{w}(x) \cdot \mathbf{e} \|d\xi \, dx (6.77)
\]

Proceeding as before we get

\[
\lim_{\epsilon_n \to 0} A^* \leq \lim_{\epsilon_n \to 0} \int_0^1 \frac{1}{\omega_2} \int_{D \times H_1(0)} \chi_D(\tau) \chi_D(\tau) (x + s \epsilon_n \xi) \|J(\xi)\| \| \mathcal{E} \mathbf{w}(x + s \epsilon_n \xi) \| \| \mathcal{E} \mathbf{w}(x + s \epsilon_n \xi) \|^2 d\xi d\tau ds
\]

\[
= \int_0^1 \frac{1}{\omega_2} \int_{H_1(0)} \chi_D(\tau) (x + s \epsilon_n \xi) \|J(\xi)\| \| \mathcal{E} \mathbf{w}(x + s \epsilon_n \xi) \| \| \mathcal{E} \mathbf{w}(x + s \epsilon_n \xi) \|^2 d\xi d\tau ds
\]

\[
= 0,
\]

where we use Lebesgue bounded convergence to interchange limit and integral and the point wise limit holds a.e. \( x \in D_{\beta}(\tau) \) at the Lebesgue points

\[
\lim_{\epsilon_n \to 0} \frac{1}{\omega_2} \int_{H_1(0)} \|J(\xi)\| \| \mathcal{E} \mathbf{w}(x + s \epsilon_n \xi) \| \| \mathcal{E} \mathbf{w}(x + s \epsilon_n \xi) \|^2 d\xi = 0,
\]

This establishes strong convergence for \( \mathbf{w} \in W^+(D_{\beta}(\tau)) \). Collecting results gives that the limit of the first term on the right hand side of (6.70) is

\[
\lim_{\epsilon_n \to 0} \int_0^T \varphi(t) I^n dt = - \int_0^T \varphi(t) \int_D \mathcal{E} \mathbf{u}^0 : \mathcal{E} \mathbf{w} \, dx dt.
\]

Passing to the limit on the last term of the right hand side of (6.70) and arguments similar to before give

\[
\lim_{\epsilon_n \to 0} \int_0^T \int_D \mathbf{b}^* \cdot \mathbf{w} \, dx \varphi(t) dt = \int_\partial D \mathbf{g} \cdot \mathbf{w} \, ds \varphi(t) dt.
\]

and we conclude that

\[
\int_\tau^T \varphi(t) \rho(\mathbf{u}^0(t), \mathbf{w}) \, dt = - \int_\tau^T \varphi(t) \left( \int_D \mathcal{E} \mathbf{u}^0 : \mathcal{E} \mathbf{w} \, dx + \int_{\partial D} \mathbf{g} \cdot \mathbf{w} \, ds \right) dt,
\]

for all \( \mathbf{w} \in W^+(D_{\beta}(\tau)) \) and lemma 6.2 is proved.

7 Weak solution of the wave equation on \( D_t \)

Theorem 3.3 is proved in this section. From theorem 3.1 and lemma 3.2 the limit displacement \( \mathbf{u}^0 \) belongs to \( \mathcal{V} \). From lemma 2.8 and remark 2.9 of [10] we have that if \( \mathbf{u} \in \mathcal{V} \) and (3.28) holds for every \( \varphi \in C^\infty_c((0, T); \mathcal{V}) \) with \( \varphi(t) \in \mathcal{V}_t \) then \( \mathbf{u} \) is a weak solution of (3.28). Motivated by this we begin by selecting a class of trial fields that are convenient to work with. For \( t \in [0, T] \) take \( s_\beta(t) = t - \beta \)
and given $w \in C^\infty((0, T); V_T)$ with $w \in V_\ell$ for $t \in (0, T)$. Set $\tilde{w}(t) = w(s_\beta(t)) \in V_{s_\beta(t)} \subset V_\ell$ for some $\beta \in (0, t)$. Substitution of this trial in (2.44) gives the identity

$$
\int_0^T \int_D \dot{u}^\epsilon(t) \cdot \hat{w}(t) \, dx \, dt = \int_0^T \int_D \int_{H_n(x) \cap D} |y - x| \partial_S W^\epsilon_n(S(y, x, u^\epsilon_n(t)))S(y, x, \hat{w}(t)) \, dy \, dx \, dt - \int_0^T \int_D b^\epsilon_n(t) \cdot \hat{w}(t) \, dx \, dt,
$$

for $\epsilon > 0$. Here we will pass to the $\epsilon_n = 0$ limit in this identity to obtain an $\epsilon_n = 0$ identity. Then on passing to the $\beta \to 0$ limit in each term we will show that $\hat{w}$ is a weak solution. We begin by understanding the limit of the middle term in (7.1) for a given sequence indexed by $\epsilon_n$. We write out the integrand appearing under the time integral

$$
I_n(t, \tilde{w}(t)) = \int_0^T \int_{H_n(x) \cap D} |y - x| \partial_S W^\epsilon_n(S(y, x, u^\epsilon_n(t)))S(y, x, \tilde{w}(t)) \, dy \, dx.
$$

and identify the point-wise limit $\lim_{\epsilon_n \to 0} I_n(t, \tilde{w}(t))$ for a.e. $t \in (0, T)$. For this choice of test function we change variables as in (6.32) to obtain

$$
I_n(t, \tilde{w}) = I_1^\epsilon(t, \tilde{w}) + I_2^\epsilon(t, \tilde{w}),
$$

where

$$
I_1^\epsilon(t, \tilde{w}) = -\frac{1}{\omega_2} \int_{D \times H_1(0)} \omega(x, \epsilon_n x) |J(|\xi|)h' \left( \epsilon_n |\xi| |D^\epsilon_n[|\xi|u^\epsilon_n - e^\epsilon_n|^2} \right) \times 2(D^\epsilon_n[|\xi|u^\epsilon_n - e^\epsilon_n)(D^\epsilon_n[|\xi|\tilde{w} - e^\epsilon_n) \, d\xi \, dx,
$$

and

$$
I_2^\epsilon(t, \tilde{w}) = -\frac{1}{\omega_2} \int_{D \times H_1(0)} \omega(x, \epsilon_n x) \chi(x, x + \epsilon_n x) |J(|\xi|)h' \left( \epsilon_n |\xi| |D^\epsilon_n[|\xi|u^\epsilon_n - e^\epsilon_n|^2} \right) \times 2(D^\epsilon_n[|\xi|u^\epsilon_n - e^\epsilon_n)(D^\epsilon_n[|\xi|\tilde{w} - e^\epsilon_n) \, d\xi \, dx,
$$

As in (6.60) we have

$$
I_1^\epsilon(t, \tilde{w}) = -\frac{1}{\omega_2} \int_{D \times H_1(0)} \omega(x, \epsilon_n x) \chi(x, x + \epsilon_n x) |J(|\xi|)h' \left( \epsilon_n |\xi| |D^\epsilon_n[|\xi|u^\epsilon_n - e^\epsilon_n|^2} \right) \times 2(D^\epsilon_n[|\xi|u^\epsilon_n - e^\epsilon_n)(D^\epsilon_n[|\xi|\tilde{w} - e^\epsilon_n) \, d\xi \, dx,
$$

where

$$
\chi(x, x + \epsilon_n x) = \begin{cases} 
0, & \text{if the points } x, x + \epsilon_n x \text{ are separated by } \{0 \leq x_1 \leq \ell^\beta(t - \beta), \ x_2 = 0\} \\
1, & \text{otherwise},
\end{cases}
$$

for $n$ large enough so that $\ell^\beta(t - \beta) < \ell^\epsilon_n(t)$ and $0 < \epsilon_n < (\ell^\beta(t) - \ell^\beta(t - \beta))/2$, where $\beta \in (0, t)$. (Here we have used that $\ell^\beta(t)$ is continuous and strictly increasing.) As before the integrand is the product of two factors such that the first factor

$$
\omega(x, \epsilon_n x) \chi(x, x + \epsilon_n x) h' \left( \epsilon_n |\xi| |D^\epsilon_n[|\xi|u^\epsilon_n - e^\epsilon_n|^2 \right) \times 2(D^\epsilon_n[|\xi|u^\epsilon_n - e^\epsilon_n)(D^\epsilon_n[|\xi|\tilde{w} - e^\epsilon_n) \to 2h'(0)g(x, \xi, t)
$$

weakly in $L^2(D \times H_1(0), \mathbb{R})$ and the second factor

$$
\omega(x, \epsilon_n x) \chi(x, x + \epsilon_n x) D^\epsilon_n[|\xi|\tilde{w} - e^\epsilon_n \to E\tilde{w}(x)e \cdot e.
$$
strong in $L^2(D \times \mathcal{H}_1(0), \mathbb{R})$. Hence we conclude using the same arguments given in the proof of lemma 6.2 that

$$\lim_{\epsilon_n \to 0} I_1^{\epsilon_n}(t, \hat{w}) = - \int_D \mathcal{C} \mathcal{E} u^0(t) : \mathcal{E} \hat{w} \, dx. \quad (7.9)$$

For $\hat{w} \in V_{\delta(t)}$ and hypothesis 3.1 and since $\ell(t)$ is strictly increasing and continuous it is evident that for $\epsilon_n$ sufficiently small, $\hat{w}$ is continuous on almost all lines that intersect $\{SZ^{\epsilon_n} \setminus FZ^{\epsilon_n}\}$. From hypothesis 3.1 noting that $\ell(t)$ is strictly increasing and continuous, we find after a simple calculation that $|\{SZ^{\epsilon_n} \setminus FZ^{\epsilon_n}\}| \leq C|\epsilon_n|^2$. We estimate $I_2^{\epsilon_n}(t, \hat{w})$ as in (6.42)

$$|I_2^{\epsilon_n}(t, \hat{w})| \leq \frac{1}{\rho \omega_2} \int_D \mathcal{C} \mathcal{E} u^0(t) : \mathcal{E} \hat{w} \, dx. \quad (7.10)$$

From this we conclude that $\lim_{\epsilon_n \to 0} I^{\epsilon_n}(t, \hat{w})$ exists and

$$\lim_{\epsilon_n \to 0} I^{\epsilon_n}(t, \hat{w}) = - \int_D \mathcal{C} \mathcal{E} u^0(t) : \mathcal{E} \hat{w} \, dx, \quad (7.11)$$

for $\hat{w} \in V_{\delta(t)}$ for a.e. $t \in (0, T)$. Arguments identical to the proof of theorem 5.2 show that for $\hat{w} \in V_{\delta(t)}$ we have

$$|I^{\epsilon_n}(t, \hat{w})| \leq C\|\hat{w}\|_{V_{\delta(t)}}. \quad (7.12)$$

We form

$$\int_0^T I^{\epsilon_n}(t, \hat{w}(t)) \, dt. \quad (7.13)$$

One then sees from definition 3.1 that $\|\hat{w}(t)\|_{V_{\delta(t)}}$ is integrable and from (7.12) we can apply the Lebesgue dominated convergence theorem to conclude

$$\lim_{\epsilon_n \to 0} \int_0^T I^{\epsilon_n}(t, \hat{w}(t)) \, dt = - \int_0^T \int_D \mathcal{C} \mathcal{E} u^0(t) : \mathcal{E} \hat{w}(t) \, dx \, dt. \quad (7.14)$$

It is first noted that lemma 3.1 can be extended in a straight forward way to the present context. Applying this to the last term in (7.14) gives

$$- \lim_{\epsilon_n \to 0} \int_0^T \int_D b^{\epsilon_n}(t) \cdot \hat{w}(t) \, dx \, dt = - \int_0^T \int_{\partial D} g(t) \cdot \hat{w}(t) \, d\sigma \, dt. \quad (7.15)$$

We apply lemma 3.2 to the first term of (7.14) and pass to a subsequence if necessary to find that

$$\lim_{\epsilon_n \to 0} \rho \int_0^T \int_D \hat{u}^{\epsilon_n}(t) \cdot \hat{w}(t) \, dx \, dt = \rho \int_0^T \int_D \hat{u}^0(t) \cdot \hat{w}(t) \, dx \, dt. \quad (7.16)$$

On again passing to a subsequence if necessary we recover

$$- \int_0^T \rho \int_D \hat{u}(t) \cdot \hat{w}(t) \, dx \, dt + \int_0^T \int_D \mathcal{C} \mathcal{E} u^0(t) : \mathcal{E} \hat{w}(t) \, dx \, dt = \int_0^T \int_{\partial D} g(t) \cdot \hat{w}(t) \, d\sigma \, dt, \quad (7.17)$$

28
where \( \tilde{w}(t) = w(s_\beta(t)) = w(t - \beta) \in V_{s_\beta(t)} \) for a.e. \( t \in [0, T] \). Given that \( w(t) \in C^\infty_c(0, T; V_T) \) we see that
\[
\lim_{\beta \to 0} \rho \int_0^T \int_D w^0(t) \cdot \tilde{w}(t - \beta) dx \, dt = \rho \int_0^T \int_D u^0(t) \cdot \dot{w}(t) dx \, dt.
\]
(7.18)
Similarly
\[
- \lim_{\beta \to 0} \int_0^T \int_{\partial D} g^0(t) \cdot \tilde{w}(t) d\sigma \, dt = - \int_0^T \int_{\partial D} g(t) \cdot w(t) d\sigma \, dt.
\]
(7.19)
To finish the proof we show \( \lim_{\beta \to 0} w(s_\beta(t)) = w(t) \) in \( V_t \), a.e. for \( t \in [0, T] \). We use the following lemma proved in [9].

**Lemma 7.1.** Let \( \{V_t\}_{t \in [0, T]} \) be an increasing family of closed linear subspaces of a separable Hilbert space \( V \). Then, there exists a countable set \( S \subset [0, T] \) such that for all \( t \in [0, T] \setminus S \), we have
\[
V_t = \bigcup_{s < t} V_s.
\]
(7.20)
Observe that
\[
\bigcup_{0 < s \beta(t)} V_{s_\beta(t)} = \bigcup_{s < t} V_s,
\]
(7.21)
so \( \lim_{\beta \to 0} w(s_\beta(t)) = w(t) \) in \( V_t \), a.e. for \( t \in [0, T] \), hence
\[
\lim_{\beta \to 0} \int_0^T \int_D C \mathcal{E} u^0(t) : \mathcal{E} \tilde{w}(t) \, dx = \int_0^T \int_D C \mathcal{E} u^0(t) : \mathcal{E} w(t) \, dx.
\]
(7.22)
Since \( u^0 \in V \) it is also clear from Cauchy’s inequality applied to (7.11) that for \( \beta > 0 \) that
\[
\left| \int_0^T \int_D C \mathcal{E} u^0(t) : \mathcal{E} \tilde{w}(t) \, dx \right| \leq C\|w(t)\|_{V_T},
\]
(7.23)
and
\[
\lim_{\beta \to 0} \int_0^T \int_D C \mathcal{E} u^0(t) : \mathcal{E} \tilde{w}(t) \, dx \, dt = \int_0^T \int_D C \mathcal{E} u^0(t) : \mathcal{E} w(t) \, dx \, dt.
\]
(7.24)
follows from the Lesbegue dominated convergence theorem. Collecting results we have
\[
- \int_0^T \rho \int_D \dot{u}(t) \cdot \dot{w}(t) \, dx \, dt + \int_0^T \int_D \mathcal{E} u(t) : \mathcal{E} \dot{w}(t) \, dx \, dt = \int_0^T \int_{\partial D} g(t) \cdot w(t) d\sigma \, dt,
\]
(7.25)
for all \( w \in C^\infty_c((0, T); V_T) \) with \( w(t) \in V_t \) and theorem 3.4. is proved.

### 8 Conclusions

In this paper we use a double well energy within a peridynamic formulation. We provide the boundary value problem satisfied by the limit displacement \( u^0 \). The limit displacement \( u^0(\cdot, t) \) satisfies the boundary conditions of the dynamic brittle fracture problem given by

- Prescribed inhomogeneous traction boundary conditions.
- Balance of linear momentum as described by the linear elastic wave equation.
- Zero traction on the sides of the evolving crack.
- Displacement jumps can only occur inside the crack set \( \Gamma_t \).
In this way the boundary value problem for the elastic field for dynamic Linear Elastic Fracture Mechanics (LEFM) is recovered as described in [14], [27], [2], [33]. Moreover the limit displacement $u^0$ is a weak solution of the wave equation on the time dependent domain $D_t$ containing the running crack. This establishes a rigorous connection between the nonlocal fracture formulation using a peridynamic model derived from a double well potential and the wave equation posed on cracking domains given in [10].

One can assume a more general crack structure for the nonlocal model and pass to the local limit to see that the nonlocal elastic displacements converge to limits that are weak solutions to the wave equation on a more general cracking domain. As an example we change body forces and initial conditions as appropriate and consider a pice-wise smooth curve $\Gamma \subset D$ of length $L$ originating at the the notch $(x_1 = \ell(0), x_2 = 0)$ containing all nonlocal crack centerlines for $t \in [0, T]$. For a given horizon the crack centerline at time $t$ is characterized by the curve $J^\epsilon(t)$ originating at the notch $(x_1 = \ell(0), x_2 = 0)$ of length $\sigma^\epsilon(t)$ at time $t$. The centerline length grows and is assumed to be an increasing function in time. The failure zone is defined as

$$FZ^\epsilon(t) = \{ x \in D, \xi \in H_1(0) : x = y + \epsilon \xi, \text{ and } y \in J^\epsilon(t) \}. \quad (8.1)$$

We introduce the curve $\tilde{J}^\epsilon(t)$ lying on $\Gamma$ and containing $J^\epsilon(t)$ with length $\sigma^\epsilon + C \epsilon$ and the softening zone is defined by

$$SZ^\epsilon(t) = \{ x \in D, \xi \in H_1(0) : x = y + \epsilon \xi, \text{ and } y \in \tilde{J}^\epsilon(t) \}, \quad (8.2)$$

where $FZ^\epsilon(t) \subset SZ^\epsilon(t)$. As before we can pass to a subsequence $\epsilon_n \to 0$ to find an increasing distance $\sigma^0(t)$. Lemma [5.1] extends to this case and additionally when $\sigma^0(t)$ is continuous and strictly increasing we apply arguments identical to those given in section [7] to show that the limit displacement $u^0(t)$ is the weak solution to the wave equation inside the cracking domain. More generally it is conjectured that nonlocal elastodynamics converge to weak solutions of the wave equation for growing cracks described by closed countably rectifiable subsets of $D$ with bounded one dimensional Hausdorff measure.
